**Banquet in Honor of Dr. Gregory.**—The medical profession of St. Louis, under the auspices of the St. Louis Medical Society, will give a testimonial banquet to Dr. Elisha H. Gregory, who for fifty years has been an active teacher of medicine, probably longer than any other man living. The banquet will be held at the Planters' House on April 17. A large number of guests will be invited, including all the ex-presidents of the American Medical Association, out of compliment to Dr. Gregory, who was president of the Association in 1886-1887. A committee composed of Drs. F. J. Lutz, N. B. Carson, J. P. Bryson, C. H. Hughes, W. B. Outten and H. W. Loeb, has the matter in charge.

**Finding of the Tetanus Court.**—As a result of the investigation to fix the responsibility for the 13 deaths from tetanus following the injection of anti-diphtheric serum in St. Louis, the committee, consisting of the Board of Health and a committee from the city council made the following report:

Pursuant to the resolution adopted by the Board of Health on Nov. 25, 1901, in reference to investigating the responsibility of the Health Department as charged in the coroner's verdict in regard to the deaths from the use of diphtheria antitoxin, prepared and distributed gratuitously by the city, the board, after having made, jointly with a committee of the city council, a searching and complete investigation of the matter, does find:

1. That the diphtheria antitoxin heretofore issued by the city was prepared, bottled and distributed by and under the supervision of Dr. Amand Ravold, who was employed by the Health Commissioner, with the approval of the Board of Health, in 1894, as consulting bacteriologist, and to have charge of the preparation and distribution of diphtheria antitoxin, and that he was responsible for the quality of material so prepared and distributed.

2. That a horse kept by the city under the supervision of Dr. Ravold, as a producer of diphtheria antitoxin serum, was bled by him Sept. 29, 1901, and on October 2 was found to have tetanus and was killed.

3. From Dr. Amand Ravold's testimony, the poisonous character of the serum from this bleeding of September 29 was known to him, but he failed to cause the serum to be destroyed.

4. That, owing to this inexcusable negligence, the poisonous serum was, in part, bottled and issued to physicians between October 10 and 23, with the deplorable results which instigated the coroner's investigation.

5. That the bottling of the serum proven to be poisonous was done by Henry Taylor, who was janitor of the City Chemist's office, and assistant, at the time, to Dr. Ravold in the work of preparing the serum for issuance.

6. That it does not appear that Henry Taylor was aware of the poisonous character of the serum at the time, but that his course is reprehensible in that he obscured and retarded the investigation by conflicting statements under oath.

In view of the foregoing finding, the board recommends that Dr. Amand Ravold and Henry Taylor be dismissed from the service of the Health Department. And the board further recommends that the city do not hereafter manufacture diphtheria antitoxin.

#### NEW YORK.

**Opening of Syracuse Hospital.**—The reconstructed Hospital of the Good Shepherd, Syracuse, was formally opened, February 4. The president announced that William B. Cogswell had given \$100,000 to the hospital and had also loaned the institution \$100,000 without interest during his lifetime.

**Personal.**—Dr. Henry L. Elsner, Syracuse, addressed the medical section of the Buffalo Academy of Medicine on "Pneumococci Cardiac Toxemia and Its Treatment." He was entertained at dinner by Dr. Julius Ullman.—Dr. Charles G. Stockton and wife, Buffalo, sailed for Europe on the S. S. *Celtic*. They expect to go to Egypt by way of the Mediterranean and will return about the middle of April.—Dr. John Byrne, of Brooklyn, and his wife, overcome with grief at the death of seven of their children from consumption, have left their old home in Clinton Street, and have gone to Europe for an indefinite period.

**Compulsory Vaccination.**—Apropos of the announcement that there are many new cases of smallpox in New York City, comes word that a bill is now before the legislature, making vaccination compulsory. It provides that local boards of health shall enforce the law regarding vaccination in the case of all policemen, firemen, school-teachers and public officers generally; that no person is to be admitted to the National Guard without a certificate of having been successfully vaccinated within five years, and that no firm or corporation employing more than ten persons shall have in their employ anyone who has not been vaccinated within five years. Violation of these provisions is made a misdemeanor, punishable by a fine of not less than \$50 or more than \$100.

**State Cancer Laboratory.**—The new state laboratory for the investigation of cancer in Buffalo has been removed into the building donated through the generosity of Mrs. Gratwick. It is a three-story fireproof structure located on High Street, directly opposite the General Hospital. The first floor has a large laboratory and several private laboratories. The second floor has offices, a library, the private laboratory of Dr. Gaylord and the chemical laboratories. The third floor has the bacteriological laboratory, incubation room, a perfectly equipped room with skylight for photography and its dark room, and another room for microphotography. The lighting of all the laboratories is perfect, and they are all fitted with modern appliances. Dr. Gaylord and his associates are to be congratulated on their new home, and New York State may well feel proud of giving its support to scientific research work. The community and the medical profession owe Dr. Roswell Park gratitude, as he was the one who first undertook the establishment of this institution.

**Amalgamation of Medical Organizations.**—The New York State Medical Association, on February 7, passed the following resolution, appointing a committee on conference: "Whereas, the Medical Society of the State of New York, having appointed a committee to confer with a similar committee from the New York State Medical Association, with the view to a union of the two organizations, and notice of such creation of a committee having been officially given to our President, together with a request that a corresponding committee be appointed by us; therefore, be it resolved that this Council (the executive board of the Association) appoint for the purpose of the conference in question, a committee of five, consisting of Dr. E. Eliot Harris as chairman, and Drs. William H. Biggam, Emil Mayer, Parker Syms, and Frederick Holme Wiggin, to which committee the President is added as a member ex-officio." The committee representing the Medical Society of the State

of New York consists of Dr. Abraham Jacobi, New York; Dr. Albert Vander Veer, Albany; Dr. Abel M. Phelps, New York; and Dr. George R. Fowler, Brooklyn.

#### New York City.

**St. Catherine's Hospital, Brooklyn,** at its annual election selected the following officers for its medical board: Dr. Ferdinand G. Kneer, New York, president; Dr. Peter G. Hughes, Brooklyn, vice president; Dr. Maurice Enright, Brooklyn, secretary, and Drs. Matthias Figueria, Kneer and Enright, executive committee. Separate tuberculosis pavilions are to be added to the hospital this year.

**German Hospital Prospects.**—During 1901, 3398 patients were treated at this institution, of whom 2695 were non-paying. In the dispensary 21,504 patients were treated in 63,274 visits. The new building, which brings up the capacity of the hospital to 245 beds, was completed in December. Four of the five stories of the building have been dedicated to the memory of deceased friends on payment of \$25,000 per floor. Dr. Florian Krug was elected to the medical board in place of Dr. Otto G. T. Kiliani.

**New Site for the Woman's Hospital.**—Although an option was held on property fronting on Amsterdam Avenue between 109th and 110th Streets, it is now announced that a plot of ground situated in this block, but 200 feet from the avenue, has been purchased by the hospital. There is a frontage of 300 feet on each street, so that 60,000 square feet of space is at the disposal of the architect. The trustees are said to have paid nearly \$250,000 for the land, but as they will receive \$450,000 for their present site, there will be a handsome balance toward the building fund. The building is to be five or six stories high.

#### PENNSYLVANIA.

**Osteopath Held.**—An osteopath of Meadville, arrested on the charge of practicing medicine without a license, has been bound over to the Quarter Sessions Court in \$1000 bail.

**Homestead Water Condemned.**—At a meeting of the local society, February 6, the water supply of Homestead was condemned and a committee consisting of Drs. John Purman, Elmer E. Wible and Edward H. Wood appointed to examine and prepare a report on the subject.

**Norristown Hospital vs. Philadelphia County.**—In the suit of the trustees of the State Hospital for the Insane at Norristown against the County of Philadelphia to recover for board, clothing and treatment for indigent insane during 1896, a verdict was rendered in favor of the plaintiff for \$67,508.

**St. Vincent's Hospital, Erie.**—At the annual meeting of the trustees, Dr. Chester W. Stranahan was elected consulting physician; Drs. Frank A. Walsh, Thomas Purcell, Charles A. O'Dea and Wallace R. Hunter were elected assistant physicians, and Drs. James H. Delaney and B. D. Schlaudecker, specialists. The bequest of \$6000 to the hospital by the late Ada A. Mehl has been cut down by order of the Orphans' Court to \$1503.

#### Philadelphia.

**The Philadelphia Neurological Society** will hold a meeting, February 25, 8:15 p. m. Dr. Adolph Meyer, director of the Pathological Institute for the New York State Hospitals will, by invitation, deliver an address entitled "Conditions for Psychiatric Research." Members of the profession are cordially invited to attend. After the address a reception will be tendered Dr. Meyer at the University Club.

**Nathan Lewis Hatfield Prize for Original Research in Medicine.**—The College of Physicians of Philadelphia announces that the sum of \$500 will be awarded to the author of the best essay in competition for the above prize on the subject "The Relation between Chronic Suppurative Processes and Forms of Anemia." Essays must be submitted on or before March 1, 1903. The competition is open to members of the medical profession and men of science in the United States. Address for particulars, J. C. Wilson, M.D., 219 South 13th Street, Philadelphia.

**Quarantine to Be Raised.**—Dr. John V. Shoemaker, president of the Department of Charities, has recommended to the Department of Public Safety that quarantine, where established in the city, be raised, and that its practice be discontinued. He considers fumigation, sunshine and plenty of fresh air much more effectual as remedies than the close and continuous quarantining of houses. Dr. Shoemaker cites the fact that London some time since gave up quarantining, and that large cities in this country are beginning to recognize the greater efficiency of fumigation.

**New Hospital for Jefferson.**—Plans are nearing completion by the trustees of Jefferson Medical College by which a new hospital will be built soon. It is proposed to construct a fireproof, seven-story building, fronting on 10th Street, including the site of the old college. There will be space for 250 to 275 beds. Provision will be made for equipment for treatment by the most modern methods. A gymnasium will be provided for the treatment of deformities; sun-parlors will communicate with each ward, and a roof garden will cover the entire building. Provision is made for the J. M. Da Costa Clinical Laboratory and Amphitheater, which will be a gift to the institution from the alumni and friends of Dr. Da Costa.

**Medical Laboratories.**—The trustees of the University of Pennsylvania have contracted for the erection of medical laboratories, which, it is claimed, will be the largest and most complete in the United States. It is proposed to expend \$600,000 upon the building and equipment. Half the sum, including a recent gift of \$75,000, is now in hand. The building will be 245 by 340 feet, and two stories in height. It is to contain amphitheaters, demonstration rooms, and physiological, pharmacodynamic, pathological and histological laboratories. An unusual quantity of glass will be used in providing for lighting, and the halls, corridors, and stairways will have floors and wainscoting of marble.

**Typhoid Fever and Smallpox Situation.**—The typhoid fever and smallpox situation showed improvement last week. Of the former there were in the city 154 new cases, of the latter 75. A committee of experts, consisting of Drs. Shoemaker, Tyson, Hare, Henry and Anders recently submitted a report, regarding the quarantining of smallpox, to the Department of Public Safety. The suggestions, which are as follows, were adopted by the department: That as soon as a case of smallpox be diagnosed the patient be sent to the municipal hospital; that the house from which the patient is removed be thoroughly disinfected; that as soon as the inmates of the premises are vaccinated, they be given their liberty. Strict quarantining of the inmates for 18 days has previously been observed. Much, perhaps the whole of the city, is to be re-canvassed by the special vaccine corps; lodging-house inmates are being vaccinated at night. The smallpox epidemic will probably cost the city \$500,000.

**Money for Hospitals.**—By the will of the late J. Alfred Kay, the following institutions receive \$5,000 each: Pennsylvania Hospital, Germantown Hospital, University Hospital, Jefferson Hospital, Orthopedic Hospital and Polyclinic Hospital, for the purposes of endowing free beds in each institution in memory of Mary Kay. With certain provisions regarding the death of a niece, to whom is left the net income of the balance of the estate, in case she dies without issue, the residuary estate, less \$15,000, is to be equally divided among the hospitals already mentioned. Of this amount, \$11,000 will be divided in portions of \$1000 each among the following hospitals: St. Agnes' Hospital, St. Joseph's Hospital, Jewish Hospital, Presbyterian Hospital, Philadelphia Dispensary, German Hospital, Gynecean Hospital, Howard Hospital and Infirmary, Medico-Chirurgical Hospital, Church Home for Children, and Children's Hospital. Germantown Hospital has received a bequest of \$1000 by the will of the late Katharine P. Bockius.

**Personal.**—Drs. J. W. Kline, J. A. Davis, Aaron G. Miller and E. L. Kiesel have been elected to the medical staff of the German Hospital.—The Department of Charities and Corrections has appointed the following outdoor physicians: Drs. Daniel A. Modell, W. E. Morgan, J. Winslow Longfellow and William H. Semple.—Dr. Sherborne W. Dougherty has been appointed medical inspector in the Philadelphia postoffice, succeeding Dr. James B. Harmer.—Dr. Jonathan C. Biddle has been re-elected superintendent and chief surgeon of the State Hospital for Injured Persons, Fountain Springs.—Through a private letter it is learned that Dr. Keen, ex-president of the American Medical Association, and daughters, have reached Benares, on their way around the world. They started on the journey traveling westward, after attending the Association meeting at St. Paul last June. While in Burnah Dr. Keen had the misfortune to suffer a fracture of the clavicle, from which he had nearly recovered on last reports.—Dr. George E. de Schweinitz, professor of ophthalmology in Jefferson Medical College, has recently been elected to the chair of ophthalmology in the University of Pennsylvania, made vacant by the death of Professor Norris a few months ago. It is reported that Dr. de Schweinitz will accept the new position. He will thereby return to his alma mater.

## GENERAL.

**The Woman's Medical Journal.**—This journal enters on its twelfth volume with the January number in an entirely new form and general "get up." It bears every evidence of prosperity and of the fact that it is well managed both from the business and editorial side.

**Liberal Prizes by a Pharmaceutical Firm.**—Cash awards are being offered by the Maltine Company, Brooklyn, N. Y., for the two best essays on preventive medicine. The liberality of the prizes, \$1000 for the first and \$500 for the second, will, no doubt, bring meritorious articles into the competition. While the firm does not so state, it is assumed that the essays will be published and presented to the profession, thus doing good generally. The three judges are well-known and reputable physicians. One of the restrictions governing the competition is that no mention of the preparation in which the house is interested be made, either directly or indirectly.

## CANADA.

**Personals.**—Dr. A. D. McIntyre has been appointed house surgeon at the Kingston General Hospital to succeed Dr. Grimshaw, who has gone to England for a post-graduate course.—Dr. J. R. Lancaster, who has been practicing at Tilsonburg, Ont., for the past seven years, has been appointed house surgeon at Grace Hospital, Toronto.

**Dr. J. A. Fife**, one of the oldest practitioners of Peterboro, Ont., died there on the morning of February 12. Dr. Fife was born in the County of Peterboro in 1838 and received his medical education at the Toronto School of Medicine and his degree from Victoria University, Toronto. Subsequently he took a post-graduate course at Bellevue. During the American Civil war he served for two years in the Northern navy as surgeon.

**Toronto University's New Medical Building.**—Dr. R. A. Reeve, Dean of the Medical Faculty of Toronto University, headed a deputation to the Ontario Government during the past week with a view to obtaining a grant of \$50,000 toward the proposed new physiologic building which it is proposed to erect in the Queen's Park along with the other university buildings. The estimated cost of the new building is \$125,000 and it is proposed that the Arts Department carry one-third of the expense, hence the appeal to the government.

**The Efficacy of Vaccination.**—According to Dr. J. E. Laperge, of the Contagious Diseases Hospital, Montreal, the efficacy of vaccination as a preventive of smallpox has been abundantly proven within the last year in that city. Since May last there have been in the City of Montreal Contagious Diseases Hospital 240 cases of smallpox, and in no instance had a single patient been vaccinated. In addition to these there was a staff of eighteen persons, physicians and nurses, who for these months have been in daily and hourly contact with these smallpox patients, but not one of them has ever contracted the disease. The order issued to municipalities throughout the province of Quebec has been fairly well obeyed, and three hundred and forty-seven municipalities have so far adopted the prescribed by-law with regard to general vaccination with its accompanying fines for non-fulfillment of same.

**Insanity Increasing in Ontario.**—The Inspector of Insane Asylums in Ontario has reported to the government that on September 30 last there were resident in the asylums of the province no less than 4604 patients. In 1890 the number was 3318. The respective population of the various asylums of the province is as follows: Toronto, 724; London, 1034; Kingston, 509; Hamilton, 1029; Mimico, 605; Brockville, 613. In comparing the relative increase of insanity with the increase in population since 1861 the report states that in that year there were in the province 1631 lunatics in government institutions and that the total population was 1,396,991, while in 1901 there were insane and idiots to the amount of 5880 when the population was 2,182,942. The population has increased in forty years at the rate of 56 per cent., while the insane and idiotic officially known have increased at the rate of 260 per cent. The ratio of insane to population in 1861 was as one to 856; in 1901, as one to 371.

**Capsular Nephrotomy at the Toronto Clinical Society.**—The Toronto Clinical Society held its regular meeting on the evening of February 5. A case of capsular nephrotomy was reported by Dr. W. P. Caven and Dr. George A. Peters; a second by Dr. Primrose, who had operated on his own case. Dr. Caven gave a detailed history of his case: A. W., a male, aged 34 years, who had suffered from migraine since childhood. In the summer of 1899 he was first told that he had Bright's disease. His kidneys were considered to be sound in 1892 when

he had been passed for life insurance. In 1896 he had a great deal of worry, and traces the commencement of his ill-health from that time. When he came under the observation of Dr. Caven a diagnosis of Bright's disease was made. The quantity of urine passed in the twenty-four hours was from 60 to 80 ounces and there was three to seven grams of albumin to the liter present. In addition to the albumin, there were hyaline, granular and fatty casts present in great abundance; urea from 1.5 to 2 per cent. On January 3, this year, he was placed under chloroform, and Dr. Peters performed encapsulation of both kidneys at the same sitting. Prior to the operation there had been a gradually increasing number of casts in the urine, but Dr. Caven stated there was none now found in the twenty-four hours. A record was shown from which it could be seen that there was no material change in the albumin, or in the quantity of urine passed or in the urea. The man was very ill for some days after the operation, but his general health lately is commencing to improve. Dr. Peters stated there was a small abscess on the neck of the patient which seemed to him might have some bearing on the case. He thought that Dr. Edebohls was preceded by Mr. Harrison, who had used this operation in cases of acute disease. Dr. Peters did not deliver the kidney through the wound as advised by Dr. Edebohls. Dr. Primrose's case occurred in a boy of 10 years of age, and the operation was performed before Edebohls' paper on the subject was published. For six months prior to the operation the boy had had general anasarca and ascites, the general edema over the body being particularly well marked on the face and extremities. Paracentesis abdominis had been performed seventeen times. Albumin was present in the urine to the extent of 1.6 per cent. On November 20 he cut down upon the right kidney in the line following Harrison's incision and drained for a fortnight. After the operation the urine gradually increased from 20 to 40 ounces and the albumin diminished to .03 per cent. On December 20 he cut down upon the left kidney and removed the kidney capsule entirely. Here he followed Edebohls' suggestion and brought the kidney out of the wound. The child was critically ill for some days, but gradually recovered, and the renal symptoms underwent remarkable recrudescence.

## FOREIGN.

**American Hospital in Paris.**—Funds have been raised, it is said, sufficient for the purchase of land, and the erection of an American hospital in Paris.

**Gruber in London.**—The Royal Inst. of Public Health invited Prof. Max Gruber, Vienna, to deliver the Harben lectures in January. His theme was "Bacteriolysis and Hemolysis."

**Fifth International Congress of Psychology.**—Professor A. Tamburini, of the Instituto Psichiatrico at Reggio nell' Emilia, is the secretary general of this congress, which is to be held at Rome in 1904.

**Title for von Bergmann.**—Kaiser Wilhelm has conferred the title of "Wirklicher Geheimer Rath" on Prof. E. von Bergmann, of Berlin. It entitles him to be called His Excellency, and is considered a great honor. It has been conferred on only two physicians before, von Langenbeck and von Esmarch.

**German Congress of Internal Medicine.**—Professor Naunyn, of Strassburg, will preside over this congress, which will convene at Wiesbaden, April 15 to 18. The main addresses will be on "Diagnosis and Treatment of Gastric Ulcer," by Ewald and Fleiner, and on "Radiotherapy," by Bie, of Copenhagen.

**The Ollier Monument.**—A Paris exchange states that the amount subscribed for the purpose of erecting a monument to the French surgeon, Ollier, of Lyons, has already reached more than 50,000 francs. The surgeons of this country, through Professor Keen, have subscribed 3217 francs, of Austria 600 francs, and of Germany 6000 francs.

**Deaths Abroad.**—Dr. Ballay, governor-general of French West Africa.—Dr. Spirido Mavrogeny Pasha, chief physician to the Sultan, died January 22, aged 83. He studied and graduated at Vienna. He was general inspector of military hospitals and held the rank of general. Dr. Mavrogeny was a linguist, and edited a medical journal in Turkish and French.

**International Conference of the Medical Press.**—The Prince of Monaco is to preside over this conference, which is to meet at Monaco, April 7, 8 and 9. The Société Médicale de Monaco is planning a splendid reception and lavish hospitality. Among the measures to be discussed are the constitution of the international committee and the protection of literary property.

**LONDON LETTER.****The Smallpox Epidemic.**

The number of patients in hospital, which has been 754, 873, and 877 in the three preceding weeks, has declined to 870; 203 new cases were admitted during the week against 261, 306, and 213 in the three preceding weeks. The deaths were 28, 45 and 55 in the preceding three weeks, but fell last week to 34. The epidemic has cost a very large sum; up to the present it has entailed a special expenditure in providing new hospitals of \$2,000,000.

**The Census of London.**

The official report on the census taken last year, so far as it refers to London, has just been issued. The area comprised covers 74,832 acres, and has a population of 4,536,541. In 1801 the population was 959,310; it has therefore increased five-fold during the century. Since 1881 a decline in the rate of increase has been in progress, the lowest rate (7.3 per cent.) being in the decade just concluded. That this rate still continues to decrease is shown by the fact that the increase from 1891 to 1896 was only 4.8 per cent., from 1896 to 1901 2.4 per cent. During the last 10 years the population has increased by 308,224, but as the natural excess of births over deaths in that period was 491,000, the loss-by migration exceeded 180,000. This migration is one of the causes of the rapid increase of suburban districts. In what is known as greater London the population increased in 10 years by 947,000. In the central parts of London the population has declined during the last 40 years in consequence of the transformation of dwelling houses into warehouses, offices and places of business.

**Treatment of Paralysis of the Upper Root of the Brachial Plexus by Muscular Transplantation.**

At the Clinical Society Mr. Tubby and Dr. J. Purnes Stewart showed a case illustrating a new method of treating old-standing paralysis of the upper root of the brachial plexus. A man, aged 57, fell on his shoulder and head two years ago. He was unconscious for an hour afterward, and on recovery was unable to use his left arm. After treatment at various hospitals without benefit he was admitted to Westminster Hospital. There were marked paralysis and atrophy about the left shoulder and upper arm, and total loss of electrical excitability in the deltoid, infraspinatus, biceps, brachialis anticus and supinator longus on the left side, and consequent inability to adduct the arm or flex the elbow. There was also some anesthesia along the outer side of the upper arm and forearm, which subsequently disappeared. These symptoms pointed to paralysis of the upper roots of the brachial plexus of the Erb-Duchenne type. Twenty months after the accident Mr. Tubby transferred part of the triceps and fixed it into the biceps with the object of restoring the power of flexion at the elbow and a month later attempted to restore power to the deltoid. Since the operation the transplanted portions of muscle have been assiduously massaged and the faradic current has been applied. There has been great improvement in the movements and in the utility of the limb. The patient can flex the elbow fairly and during flexion the transplanted part of the triceps can be felt in front of the elbow and both galvanic and faradic excitability have returned. He has not yet recovered the power of abducting the arm, but the transplanted part of the pectoralis major can also be felt to harden. At first there was a total loss of excitability both to induction shocks and to the galvanic current. Three months after operation the galvanic excitability returned and six months after faradic reaction could be demonstrated.

**Improvement in the Health of London.**

According to the returns just issued, the mean mortality of London during the decennium which has been completed was below that of 1881-90 at all periods of life. Mr. Shirley Murphy, medical officer of the London County Council, gives a table showing the mean annual number of deaths in 1891-1900 as compared with the annual number that would have occurred had the death-rates of the previous decennium been maintained. The number of lives gained and the number of lives lost at the several ages in the later period are also shown. This gain or loss is expressed in terms of "life capital," the figures being obtained by applying the "mean future life time" values, as ascertained from a London life table, to the number of lives gained or lost at each age-group. According to this calculation in the 10 years, 1891-1900, as compared with the previous decennium, there accrued a saving of 3664 lives per annum, representing an annual salvage of 118,483 of life capital. This reduction in mortality has by no means been manifested in the death-rate from all causes alike. Thus, there has been in

the later decennium, as compared with the earlier, a marked increase in the death-rate from diphtheria, cancer and influenza and a slight increase in the death-rate from a few other causes. On the other hand, there has been marked reduction in the mortality from phthisis and also from non-tuberculous respiratory diseases, and diseases of the nervous system, as well as a less strongly marked decrease in the death-rate from several other causes. The most important change for the worse is in the death-rate from cancer, which has increased during the last decennium by little less than 27 per cent. In the decennium ending with the year 1900 London experienced the lowest infantile mortality of any of the principal English towns save one, viz., Bristol. During 1900 the eastern metropolitan districts showed the highest infantile mortality, 175 per 1000 births; the northern group, the lowest, 145 per 1000, while the southern, the central, and the western groups experienced a rate of 158 per 1000.

**Improved Record of Vital Statistics.**

With the new year the method of furnishing the usual weekly returns of births and deaths has been greatly improved. The area covered is much enlarged; 74 cities and boroughs being included in place of the previous 32. Particulars of mortality are now published weekly respecting nearly one-half of the population of England and Wales. The tabular matter has been re-arranged so as to present the more salient facts in a manner as convenient as possible for reference. The classification of diseases and the list of causes of death have been improved. Several of the less important diseases are omitted and other and more definite diseases added. Certain of the terms retained (presumably because they are still in use by some medical men) are printed in italics, to show that they are either the names of symptoms merely or are otherwise objectionable. Some of the principal groups of disease have been subdivided so as to give opportunity for the more accurate classification of causes of death, hitherto sometimes ambiguously returned. Thus deaths from tuberculous phthisis are generally certified as from phthisis or consumption simply, which term includes, according to the authorized nomenclature, other diseases besides pulmonary tuberculosis. The more precise term is therefore inserted in addition to the term more commonly, but less correctly employed. So also, as an alternative for the old-fashioned but misleading *tabes mesenterica*, tuberculous peritonitis is suggested. In the past *tabes mesenterica* has been held by some to include not only tuberculous mesenteric disease, but likewise atrophy, marasmus, and certain other ailments attended by wasting which are not necessarily tuberculous. The malignant group of diseases also has been subdivided so as to distinguish the carcinomata from the sarcomata, and both of these from the numerous tribe of diseases indefinitely returned as malignant.

**Correspondence.****Is Membership in County Society Necessary for Old Members of State and National Societies?**

DENVER, COLO., Feb. 14, 1902.

*To the Editor:*—In considering the proposition for change of the by-laws of the various state societies to conform with the new requirements of the Association, might it not be well to bear in mind the legal status of those persons who already have membership in some state societies and who have not maintained their membership in county societies. It has been suggested that any proposal to forfeit the membership of such persons in either the state organizations or the American Medical Association could not be enforced lawfully, so long as these persons continue to comply with the letter of the regulations that were in effect at the time they acquired membership. I do not, of course, presume to pass upon the question so raised, but simply call attention to the fact that it has been brought forward in the discussion of the subject and that it is most likely to be tested judicially by some of the affected members in some part of the country.

It will be at once admitted that the majority of the Association members have no intention of adopting a standard which will work a hardship upon any old members who, for whatever reason, may not desire to re-enter their local or county society, while at the same time they do not wish to forfeit their existing and legally acquired membership in either the

state society or the Association. The number of members actually affected in this manner will be very small compared with the total membership of the Association. If it can be arranged that they shall continue in good standing and that the new requirements will apply only to persons who do not already hold permanent membership in the Association or in a state society, it will make the adoption of the new requirements more certain in some state societies and prevent a feeling of grievance on the part of some old and highly honored members. Such feeling of grievance, we can not but admit, would have a very substantial basis.

May it not then be wise to add to the clause affecting membership acquired through membership in the county societies a "saving clause," to this effect: "Provided, that the operation of this condition of membership shall apply only to new members and shall in no instance be so construed as to forfeit an existing, legally acquired membership in the Association." It will thus be made perfectly evident that it is the intention of the Reorganization Committee to thoroughly and effectually safeguard the privileges of all. Very respectfully,

WILLIAM P. MUNN, M.D.

### A Physician's Directory.

LAWRENCE, MASS., Feb. 3, 1902.

*To the Editor:*—I am of the opinion that a step in the right direction may be taken by establishing a system of registration followed by the publication of a "Physician's Directory" by the American Medical Association. The great danger to the medical profession is not from the quack or the promoter of a fad, but from him who has obtained a medical degree, secured a state license, perhaps has been admitted to the state society, and has been unable morally to keep up with the respectable members of the profession. Such an individual sooner or later is found out and can be easily cared for. The great majority of immoral and ignorant of those who have received medical degrees and state license do not seek admission to societies because they fear the required examination and the discussion of medical topics by regular physicians. This class, I believe, constitutes a majority of cheap contract physicians. They lower the standard and prostitute the title of Doctor of Medicine. The "quack" is recognized and classified by the people. The harm comes from him who has some right to the title of doctor other than a clear and moral right. Registration and an honest directory would do much to lessen the evil.

This would be a preliminary toward the establishment of a National Board of Health, which could in time demand a place in the cabinet for its representative. If that could be consummated a standard could be set and maintained and the question of reciprocity solved. Furthermore, an American Medical Education Society might be formed to enlighten the American Humane Education Society on some topics, and when they understand each other they could do much for humanity, because the Humane Society is an aggressive, active organization, and does much good within certain circumscribed limits. If a Medical Society had half its spirit and pugnacity it would soon make the title of Doctor of Medicine respected, and not, as it is now, a hollow mockery. Very truly yours,

JOHN T. CAHILL.

### Inhalation and Atomization.

CHICAGO, Feb. 17, 1902.

*To the Editor:*—On page 474 of THE JOURNAL of February 15, it is stated that "It is yet a question as to how much of the respiratory tract is reached by inhalations." I am surprised that the writer of the above is ignorant of the experimental work that I have done in this line. It is now positively proven that nebulized medicaments reach the pulmonary alveoli of the human lung, of the lung of dogs and of guinea-pigs. The microscopic slides which are the proof of this contention and statement are in my possession, and unquestionably prove the truth of this assertion. As far back as May 28, 1898, THE JOURNAL published an article by me on "Experimental Work

on the Penetrability of Vaporized Medicaments into the Air Passages." This proved the existence of nebulized medicaments in the lung of a human being. Since then much experimental work has been done that demonstrated the presence of nebulized medicaments in the pulmonary alveoli of dogs and guinea-pigs.

On April 12, 1897, I presented the subject before the Chicago Pathological Society, and in 1900 before the Chicago Academy of Medicine, and at both times exhibited microscopic slides to demonstrate the truth of the assertion.

In view of the foregoing, I claim that it is definitely proven that nebulized medicaments properly subdivided and administered do reach the pulmonary alveoli. I am quite aware that this statement is at variance with those found in the older books upon this subject, but such former statements can not stand as true in the light of the microscopic demonstration of the fact that they do reach the pulmonary alveoli.

HOMER M. THOMAS, M.D.

### The Proper Method of Vaccination.

SCHAEFFERTOWN, PA., Feb. 14, 1902.

*To the Editor:*—To a great many physicians a sore arm after vaccination signifies immunity, regardless of the nature of the soreness. A proper vaccination is attended with slight, or no, local or constitutional disturbances. The extreme local and constitutional disturbances, such as erysipelas, hospital gangrene, abscess, phlegmon, septicemia, pyemia, and tetanus, are due to an abrasion of the surface, admitting the entrance of the different bacteria. In my opinion the proper way to vaccinate is by means of a spring lancet, which leaves no open wound for the introduction of germs. It requires very little lymph to produce a proper vaccinia, one capillary tube being sufficient to produce half a dozen. The puncture made by the lancet is barely discernible, and leaves no abraded surface for any sort of exterior infection.

During the epidemic of 1874-75, I vaccinated, by means of the lancet, over eight hundred people of all ages—primary and secondary—and not one manifested any serious local or constitutional trouble. During the present epidemic this method has given the same satisfactory results, while those who employed the scalpel, or the needle, with the same environment and using the same lymph, have had many complications. Hence it is again to be inferred that the faulty method of operation and not the lymph employed is responsible for the sufferings and deaths due to vaccination. I wish to emphasize the erroneous technique of an abrasion by scraping, or almost cutting, of the arm; producing a good culture-medium for germs not intended. With the spring lancet, no untoward effects will ensue.

J. W. KEATH, M.D.

### Married.

JOSEPH E. HAILE, M.D., to Miss Mae Hayes, both of Kershaw, S. C., January 29.

WILLIAM F. C. HEISE, M.D., to Miss Adella von Rohr, both of Winona, Minn., February 5.

C. K. CARRUTHERS, JR., M.D., to Miss Ethelene Rowell, both of Pine Bluff, Ark., February 9.

J. RAY ALLEN, M.D., Orwell, N. Y., to Miss Ethel J. Barney, at Sandy Creek, N. Y., January 30.

SAMUEL B. POTTER, M.D., to Mrs. Sarah E. Peoples, both of Fredericktown, Ohio, January 30.

JAMES P. TUCKER, M.D., Galveston, Texas, to Miss Thelma Cooper, at Waco, Texas, January 29.

NICHOLAS C. PARRISH, M.D., Denison, Texas, to Miss Emma Ryle, at Pilot Point, Texas, January 28.

WILLIAM T. DOWDALL, M.D., Cosner, Ill., to Miss Anna Connole, of Carrollton, at Jacksonville, February 8.

ROY S. BARNSBACK, M.D., Edwardsville, Ill., to Miss Minnie E. Whitbread, at Edwardsville, Ill., February 1.

ALFRED S. JAEGER, M.D., Indianapolis, Ind., to Miss Blanche C. Keiffer, of Bronson, Mich., at Indianapolis, February 5.

## Deaths and Obituaries.

**Martin L. Herr, M.D.** University of Nashville, Tenn., 1866, chief surgeon of the Lancaster, Pa., General Hospital, one of the organizers of the Lancaster Pathological Society, member of the City, County and State Medical societies and of the American Medical Association, died of paralysis at Lancaster, Pa., February 8, aged 63. He had been on two occasions delegate to the International Medical Congress. Dr. Herr was prominent in business as well, having been director and president of a Lancaster bank, a street railway company and manufacturing companies.

**William Murray Weidman, M.D.** University of Pennsylvania, 1860, an eminent physician of Reading, Pa., died from heart trouble, February 8, aged 66. He served through the Civil war and was formerly president of the Pennsylvania Medical Society, of the Berks County Medical Society and the Reading Medical Association. Dr. Weidman was upon the staff of the State Asylum for Chronic Insane, of St. Luke's Hospital, and Reading Hospital, and was a member of the American Medical Association and the American Academy of Medicine.

**Benjamin Franklin Pope, M.D.** Albany (N. Y.) Medical College, 1861, lieutenant-colonel and deputy surgeon-general, U. S. Army, chief surgeon of the Division of the Philippines, died at Manila, February 14, after an illness of two weeks, from Bright's disease. He served as assistant surgeon in the Civil war, and at its close entered the regular establishment.

**Abijah T. Hudson, M.D.** Albany (N. Y.) Medical College, 1847, Stockton, Cal., member of the San Joaquin Medical Society, former physician in charge of the San Joaquin Hospital, surgeon of the 26th Iowa Infantry during the Civil war and one of the oldest practitioners in California, died of general debility, February 5, aged 83.

**Ira W. Baldwin, M.D.** Ohio Medical College, Cincinnati, died of apoplexy at his home in Xenia, Ohio, February 1, aged 63. He had practiced also in Spring Valley and Yellow Springs, Ohio, and in Iowa. The members of the Greene County Medical Society attended the funeral in a body.

**Nathaniel Ostrander, M.D.** Washington University, St. Louis, Mo., 1848, died at his home in Olympia, Wash., February 7, aged 83. He was one of the pioneers of the northwest, and had been mayor of Olympia and a member of the territorial legislature.

**Washington D. Jeffries, M.D.** Willamette University, Salem, Ore., 1887, who had practiced medicine for nearly fifty years in Salem, and had been a member of the legislature, died February 5, aged 63, after an illness of several years.

**Jacob A. Baird, M.D.** College of Physicians and Surgeons, Baltimore, Md., 1878, of Dunlo, Pa., while assisting two women from in front of a train, slipped in the snow and fell upon the rail, meeting instant death. He was 52 years of age.

**Armistead Peter, M.D.** National Medical College, Washington, D. C., 1861, died of heart disease on January 28 at his residence in Georgetown, D. C., aged 61. He was a member of the Medical Association of the District of Columbia.

**Thomas N. Penrose, M.D.** University of Pennsylvania, a retired medical director of the U. S. Navy, died at the U. S. Naval Hospital in Philadelphia, February 13, aged 67, from an involvement of heart and kidneys.

**Adam Trau, M.D.** University of Pennsylvania, 1861, a practitioner of Philadelphia, died, February 7, of paralysis, aged 61. He was for many years president of the German Hospital medical board.

**Joseph G. Skaro, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1882, of Minneapolis, Minn., died at a private hospital in South Minneapolis, February 9, aged 43, after a long illness.

**Edwin W. Pyle, M.D.** University of Pennsylvania, 1873, assistant surgeon at the New York Eye and Ear Hospital, died of pneumonia, February 7, at his home in Jersey City, N. J., aged 52.

**Emily A. Hill, M.D.** University of Michigan, 1886, of Bowling Green, Ohio, member of the Wood County Medical Association, died, February 7, of heart disease.

**John L. Million, M.D.** Missouri Medical College, St. Louis, 1851, died, February 14, in Springfield, Ill., where he had practiced for forty years, from pneumonia, aged 75.

**T. W. Taylor, M.D.** Starling Medical College, Columbus, Ohio, 1849, died at his home in Fountain City, Ind., February 3, of an affection of the throat, aged 82.

**Dabney Luckie, M.D.** Birmingham Medical College, 1898, of Birmingham, Ala., died, February 6, at Plant City, Fla., where he had gone for his health.

**Rupert D. Cogswell, M.D.** Northwestern University Medical School, Chicago, 1860, died at his home in Rogers, Ark., of pneumonia, January 21, aged 66.

**James L. Holbrook, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1888, died at his home in Higginsville, Mo., February 9, of pneumonia.

**Thomas C. McCord, M.D.** Medico-Chirurgical College of Philadelphia, 1898, died, February 8, at his home in Pittsburgh, Pa., of heart disease, aged 30.

**Edward H. Plank, M.D.** Jefferson Medical College, Philadelphia, 1870, died from pneumonia, February 6, at his home in Christiana, Pa., aged 50.

**Herbert E. Martin, M.D.** Central Medical College, St. Joseph, Mo., 1886, died at St. Joseph, February 7, after an illness of two years.

**John P. Stack, M.D.** Washington University, St. Louis, Mo., 1891, died at his home in East St. Louis, Ill., February 10, of pneumonia, aged 32.

**Newman W. Smith, M.D.** Berkshire Medical College, Pittsfield, Mass., 1846, a retired physician of Sublette, Ill., died at Dixon, recently.

**John B. Andrews, M.D.** Dartmouth Medical College, Hanover, N. H., 1875, died of paralysis at Lynn, Mass., February 10, aged 61.

**James Hine, M.D.** New York University, 1847, died at New Milford, Conn., February 9, aged 79, from injuries received in a fall.

**Sterling P. Bond, M.D.** Arkansas University, Little Rock, Ark., 1886, died in Mangum, O. T., February 9, of pneumonia, aged 36.

**George A. Hess, M.D.** University of Pennsylvania, 1870, of Grand Rapids, Mich., died of paralysis, February 9, aged 58.

**Samuel H. Rodman, M.D.** New York Medical College, 1863, of Huntington, N. Y., died of apoplexy, February 10, aged 64.

**Charles H. Kennedy, M.D.** University of Michigan, 1869, died at his home in Sylvania, Ohio, February 7, aged 92.

**Peter R. Cortelyou, M.D.** Bellevue Hospital Medical College, New York, 1867, died at Marietta, Ga., February 6.

**William H. C. Smith, M.D.** University of Pennsylvania, 1866, died at his home in Millville, N. J., February 12.

**Richard S. Vest, M.D.** Medical College of Virginia, died at his home near Ashland, Va., February 2, aged 76.

**Henry T. Dalgleish, M.D.** Ohio Medical College, Cincinnati, died, February 2, at Vevay, Ind., aged 42.

**James S. White, M.D.** University of Michigan, 1866, died at Hodgdon, Me., January 29, of pneumonia.

**Frederick F. Tucker, M.D.** University of Texas, 1897, of San Angelo, Texas, died, February 6.

**George W. Thomas, M.D.**, of Eatonton, Ga., died of Bright's disease, February 2, aged 64.

## Miscellany.

### Osteopathy.

The following is an abstract of the argument against the osteopath bill, made before the Judiciary Committee of the New York Legislature, by Dr. E. Eliot Harris, representing the New York State Medical Association:

The tendency of modern times is to raise, rather than to lower the standard of the educational qualifications of professional men. The public has so long suffered from poorly educated physicians that the legislatures of nearly every state in the Union have enacted laws raising the educational qualifications of the candidates to be examined for a license to practice medicine. We claim osteopathy, so-called, is an agent used in the treatment of disease, and as such has no more right or reason to be separated from the general practice of medicine than electricity, mechanical exercise, bathing, nursing, massage, or any other valuable agent or method used in the treatment of disease, and is not entitled to a special examining board. The eye, ear, nose, throat, electrotherapeutic and other

specialists do not ask exemption from the examination in the general science of medicine demanded by the Regents of the University of the State of New York, of all candidates who apply for a license to practice medicine or any branch of medicine, and they do not ask for a special examining board. If the so-called osteopaths desire to establish a special branch of medicine, then they, too, should possess at least that minimum of the knowledge of the general science of medicine demanded by the present law governing the granting of a license to practice medicine in this state; and they should not try to escape the preliminary and final examinations for a license to treat disease, by securing the enactment of the so-called osteopathic bill.

Every part of the human body is connected sympathetically with every other part; an affection of the eyes or stomach may be due to disease of the kidneys; persistent cough or pain in the knee may be due to disease in the pelvic region; eye-strain may produce pains in distant parts of the body, and so on, indefinitely. The protection of the public health demands that no one should be allowed to treat diseases in this state, unless he can make a diagnosis based on the study of the general science of medicine, as taught in the incorporated medical colleges of this state.

The medical laws of the State of New York were enacted to protect the people of the state from charlatans, quacks and pretenders of all sorts. The time spent in the study of medicine prepares the mind and molds the character along the lines of truth and science and away from commercialism in medicine. A reaction from commercialism in medicine was a factor in causing the legislature to enact the laws which prevent any person, not presenting the intellectual and moral qualifications required by the Board of Regents, from practicing medicine in this state. The public is protected by discouraging commercialism in medicine and is benefited by fostering the science of medicine.

To summarize: 1. Osteopathy, so-called, is an agent or method used in the treatment of disease, and should not be separated from the general practice of medicine.

2. Osteopathy should not be made a special branch of medicine, by an act of the legislature, but should come under the present state laws, which govern all the special branches as well as the general practice of medicine.

3. The legislature should protect the public by denying the endorsement of the state to any person, as being capable of treating the diseases of the human body, unless such person can make a diagnosis of the condition of the human body, to do which requires a full knowledge of the science of medicine, including the use of drugs and other valuable therapeutic agents.

4. If the so-called osteopathic bill becomes a law, all candidates who fail to pass the Regents' examinations to obtain a license to practice medicine in this state may in this state treat all diseases of the human body by holding a diploma from any regular osteopathic college in the United States, a privilege which a graduate from Harvard or Yale medical college, for instance, does not enjoy.

[After the hearing by the Judiciary Committee the bill was quashed by a vote of 7 to 2.]

## Societies.

**Jacksonville (Ill.) Medical Club.**—The new officers of this Club, elected January 27, are Dr. Albyn L. Adams, president; Dr. George E. Baxter, vice-president; Dr. David W. Reid, secretary; Dr. E. F. Baker, treasurer.

**Giles County (Tenn.) Medical Society.**—At the January meeting this Society elected the following officers: Dr. John S. Harris, president; Dr. John E. Bangh, vice-president; Dr. P. M. Anderson, secretary and treasurer.

**Garrard County (Ky.) Medical Society.**—At Lancaster, January 24, this Society elected these officers: Dr. Henry C. Herring, president; Dr. Elijah Evans, vice-president; Dr. Hugh M. Grant, secretary and treasurer.

**Portsmouth (N. H.) Medical Society.**—At the annual meeting, February 4, the following officers were chosen: President, Dr. Benjamin Cheever; secretary, Dr. C. W. Hannaford; treasurer, Dr. Andrew B. Sherbourne.

**Leavenworth County (Kan.) Medical Society.**—This Society, on January 23, elected Dr. John S. Weyer, president; Dr. Simon B. Langworthy, vice-president; Dr. Mayer Shoyer, secretary; Dr. Charles R. Carpenter, treasurer.

**Otsego County (N. Y.) Medical Association.**—This is a new organization, formed January 18, at Oneonta by members

of the State Association. These officers were elected: President, Dr. Julian C. Smith; vice-president, Dr. S. G. Pomeroy; secretary, Dr. Arthur H. Brownell; treasurer, Dr. Frank L. Winsor.

**Douglas County (Kan.) Medical Society.**—On January 21 this Society made preliminary plans for entertaining the State Medical Association in May. Dr. Samuel W. Williston was elected president; Dr. Elizabeth B. Laslett, vice-president; Dr. George W. Jones, secretary; Dr. Alfred Gifford, treasurer.

**Newport (R. I.) Medical Society.**—This Society's annual meeting, January 16, resulted in the election of the following: President, Dr. Christopher F. Barker; vice-president, Dr. William S. Sherman; secretary, Dr. Mary E. Baldwin; treasurer, Dr. Douglas P. A. Jacoby; librarian, Dr. Harry J. Knapp; curator, Dr. F. Jerome Davis.

**Kalamazoo (Mich.) Academy of Medicine.**—The annual meeting of this body was held at Kalamazoo, January 21, ending in a banquet in the evening. The election of officers resulted as follows: President, Dr. Charles H. McKain, Vicksburg; vice-presidents, Dr. Orton H. Clark, Kalamazoo, and Dr. Orrin F. Burroughs, Plainwell; secretary, Dr. Herman Ostrander; librarian, Dr. Edwin H. Van Deusen; treasurer, Dr. Orlo B. Ranney.

**Los Angeles County Medical Association.**—At the meeting of this Association, on February 7, at Los Angeles, the subject of Federation of Medical Societies was considered, a large number of members being present. All appeared in favor of a closer affiliation with the State and National Societies, and a committee was appointed to take up the matter and to confer with the Committee on Revision of the Constitution of the Medical Society of the State of California relative to a closer affiliation. The committee consists of Drs. W. L. Wills, G. L. Cole, W. W. Hitchcock, F. T. Bicknell, E. R. Smith, William Dodge, and C. G. Stivers, secretary.

## CINCINNATI ACADEMY OF MEDICINE.

*Regular Meeting, held Dec. 16, 1901.*

President, Dr. N. P. Dandridge, in the Chair.

### Spinal Cocainization.

DR. C. A. L. REED read a paper on this subject. His experience embraces thirty cases, including abdominal sections, curettage, reparative operations on the cervix and perineum, hemorrhoids, cystoscopic examination, and one case for the purpose of controlling irritability of the bladder.

In speaking of technique Dr. Reed emphasized the necessity of using a sterile solution and carefully locating the site for puncture. A line drawn from one crest of the ilium to the other serves as a guide with which to locate the space between the third and fourth lumbar vertebrae. The needle is inserted a little to the left and below the spine and should be directed forward and slightly inward and upward. A slight resistance is encountered when the needle touches the ligaments of the vertebrae, but this disappears when the arachnoid cavity is entered. As soon as this space is reached a few drops of clear fluid will escape through the needle. The syringe is then attached to the needle and the fluid thrown gently into the cavity. Unfortunately the puncture is not always accomplished with the facility implied by this description. Unless a local anesthetic be first applied, the pain attending the puncture may cause involuntary muscular contractions, making access to the intervertebral canal more difficult. In fat subjects the intervertebral canal is remote, and is only found after some difficulty. In a few cases the needle, after entering the intervertebral space, seems to pass to one side of the arachnoid. It has thus happened that Dr. Reed has had three "dry taps," no arachnoid fluid escaping. In one of the cases the fluid containing one-fifth grain of cocain was discharged to one side, no analgesia resulting; in a few minutes, however, alarming constitutional effects were manifest: the pulse went to 160, the respirations became exceedingly rapid, cyanosis was pronounced, prostration was extreme, while the patient's anxiety amounted to panic. In a few instances he has found that the complete consciousness that attends the anesthesia leaves the patient open to the depressing influence of the surroundings, the instruments and the operative procedures.

The complications of surgical analgesia induced by spinal injection are not more serious, while they are less constant, than those that attend the administration of chloroform or ether. Vomiting probably occurs in less than 10 per cent. of all cases, a decided improvement over the records of chloroform or ether. Syncope and headache have been observed. Spinal cocainization was offered to the profession exclusively as a surgical expedient. Our experience with it thus far has, with two exceptions, been limited to the body below the diaphragm, and usually to cases in which chloroform and ether were contraindicated, but the present trend indicates that it may be made the method of choice in preference to any general anesthetic and that the zone of its influence may be extended.

In childbirth, its use gives analgesia without diminishing the normal rhythm or force of the uterine contraction, while involution is assisted after delivery.

It is not to be supposed that the possibilities of so powerful an expedient as spinal cocainization should be limited to analgesia induced for either surgical or obstetric purposes. M. Brocard has called attention to the fact that cocain thus administered becomes an eligible remedy in sciatica, lumbago, zona, intercostal neuralgias, and in certain cases of irritable bladder. Dr. Reed's personal experience in two cases of the latter character has been very satisfactory. In one, that of a woman of 36, who was afflicted with frequent and painful urination, but in whom the cystoscope failed to reveal any local lesion, cure was effected by three spinal cocainizations.

The effort has been made to find some other agent that will produce the desired analgesia with similar effectiveness. Experiments have been made with antipyrin, tropococain and eucain, but all of them have been reported upon adversely by Bier. Jedlicks, however, reports a series of 93 cases, embracing abdominal sections, operations upon the lower extremities, perineum and scrotum, all of them done satisfactorily under eucain. Mixed injections have been given with but little advantage. In two instances he has given a quarter of a grain of morphia with the cocain, with the result of prolonging the analgesia, without producing any unpleasant effects attributable to the cocain.

The time has not yet arrived when the debit and credit sides of the account can be computed. It is to be hoped, however, that the near future will witness a systematic investigation of the results, immediate and remote, of this operation, upon which an authoritative utterance relative to its dangers or safety can be based. At the present day the statistical reports are essentially chaotic. Of the six alleged fatalities there are none that can not be explained upon a theory other than that of cocainization. The time has arrived when the complete statistics should be compiled; but in the meantime we are left with the comfortable realization that in spinal cocainization there has been added to our resources a safe means by which to induce anesthesia within certain limitations, and that its possibilities for the future are among the valuable though undetermined resources of the profession. We can accept for the present: 1, that spinal cocainization is practicable; 2, that it is relatively safe both as to immediate and future results; 3, that it is eligible in cases that can not take the general anesthetics with safety; 4, that its determined zone of influence is from the diaphragm downward; 5, that individual observations point to the possibility of general analgesia by spinal cocainization; 6, that it seems to be a safe expedient in parturition; 7, that it gives promise of a broader therapeutic applicability.

In the discussion, Dr. H. J. Whitacre dwelt upon the position of the patient. He places the patient in a perfectly erect position, an assistant holds a strand of silk across the back upon the crest of each ilium. That strand of silk goes immediately over the spine of the third lumbar vertebra. The finger is held on the apex of this spine and the patient bends forward, thus increasing the space between the laminae to give the necessary room for the insertion of the needle. Another point in the technique of importance is that of first making a minute incision with a knife. The needle which we use for the introduction of cocain may be compared to a Mixer punch.

When pushing the needle in, it is perfectly possible that we may take out a little fragment of skin and carry it in as we go along until it reaches the spinal canal, where it may set up irritation. Dr. Whitacre held that boiling the solution to sterilize it destroys its properties. The headaches, which he thinks have been proven to be due to the increased tension, will be relieved by a second puncture after the operation has been completed, allowing a small amount of fluid to escape. The suggestion has been made that such operations as fissure of the anus, hemorrhoids, etc., be done with spinal anesthesia. Considering the possibilities of danger in spinal anesthesia, I think it unjustifiable to use this means when local anesthesia by the intradermic injection of cocain will answer the same purpose. It is possible to incise a fissure under a two per cent. solution of cocain; it is possible to dilate the sphincter, not completely, but certainly sufficiently to remove hemorrhoids and to dissect out fistulae; indeed, many operations in which it would seem impossible to use this method can be performed successfully and much more safely than by spinal or general anesthesia. When these things can be done in this way it hardly seems justifiable to me to employ spinal anesthesia.

DR. FRANK W. LANGDON made some interesting observations on the order in which sensation returns to anesthetized parts.

DR. LOUIS STRICKLER said that in his experience sterilizing the cocain solution undoubtedly largely, if not entirely, destroyed its anesthesia properties. He called attention to the fact that eucain can be sterilized whereas cocain can not. His method with cocain is to sterilize the bottle and then boil the water, and on the latter cooling sufficiently to add the cocain crystals and allow them to dissolve, which is as near as he believes we can get to the sterilization of cocain.

DR. C. R. HOLMES took exception to the statement that cocain solutions become inert after sterilization. He has not used any cocain solution for twelve years that had not been sterilized by boiling, and has used it upon operations upon the eye, ear and nose thousands of times. In his experience it is the rarest thing to find that the drug is not efficacious, and in these rare cases he has regarded its lack of action to the individual idiosyncrasy of the patient. One must always bear in mind that there is a great difference in alkaloids, and my remarks have reference only to Merek's preparation, as I have used none other.

## CHICAGO MEDICAL SOCIETY AND THE CHICAGO SOCIETY OF INTERNAL MEDICINE.

*Joint Meeting, held Jan. 29, 1902.*

Dr. E. T. Wells, in the Chair.

### The Classification of Cirrhosis of the Liver.

DR. ARTHUR R. EDWARDS, after giving the classification of Rosenstein and that of Gilbert and Surmont, offered the following, with a view of including the principal conflicting clinical and pathological divisions.

I. Capsular cirrhosis. Also known as glissonian or lymphatic cirrhosis. (a) Chronic perihepatitis; isolated or part of a chronic peritonitis. (b) Portal vein syphilis (also vascular in origin).

II. Vascular cirrhosis. (a) Hepatic vein. 1. Stasis cirrhosis (cyanotic induration). 2. Cirrhosis, in (b) 1, or Laennec's cirrhosis; also Brieger and Sabourin, known as bivenous cirrhosis.

(b) Portal vein. 1. Laennec's cirrhosis or atrophic. First stage, pseudohypertrophy; second stage, atrophy. 2. Hypertrophic alcoholic cirrhosis, like Laennec's, only remaining large; fatty cirrhosis. 3. Cirrhosis from portal vein, syphilis, and from pyelothrombosis.

(c) Arteriosclerotic cirrhosis.

III. Biliary cirrhosis. (a) Obstruction—"Retentions icterus" and cirrhosis. (b) Biliary or hypertrophic, in French sense (Hanot's cirrhosis). 1. With icterus. 2. Without icterus.

IV. Mixed cirrhosis. Vascular (II) and Biliary (III) varieties combined.

DR. FRANK BILLINGS discussed "Clinical Manifestations of the Early Stage of Cirrhosis of the Liver."

### Cirrhosis in Childhood.

DR. FRANK X. WALLS said that cirrhosis of the liver was one of the most uncommon diseases occurring in infancy or childhood. The cirrhotics belong to the decadent period of life and only under the most unusual conditions are they encountered during its ascendancy. Though morbid factors be evolved within the economy of the child, that in the adult lead to a gradual parenchymatous decay and interstitial overgrowth, still in the child the nutritive and reparative powers of the individual are sufficient to sustain and restore the hepatic parenchyma, even though seriously damaged. In children who die as a result of some overwhelming sequel of the acute infectious diseases the liver is frequently found to be the seat of an extensive cellular infiltration of the connective tissue, with a granular, fatty, or even necrotic degeneration of the epithelium, and so often was this seen that one might believe there was always more or less hepatic inflammation in the severer cases of infection. Klein examined the livers in eight consecutive autopsies on scarlet fever patients and discovered acute hepatitis in all. Moreover, sufficient evidence was found in the enlarged livers and subjaundiced skins of those who recovered, to indicate that the acute hepatitis was not confined to the lethal cases. Despite the frequency of this acute hepatitis, it was most unusual to meet with a case in which there was the slow productive overgrowth of subsidiary tissue at the expense of the granular elements which constituted the morbid picture of cirrhosis. Cirrhosis was an advanced lesion, slow and tardy in its evolution, and demanded time for its development. It was so rare a disease in the young that those who had had the largest clinical experience could count their cases in the units. Baginsky had seen four cases. Henoch had never seen a fully developed case. Charles West, among 70,000 sick children, saw cirrhosis but four times. Frerich saw but one.

Male children were afflicted more often than female in the proportion of five to one. In Palmer's group, the ages varied from one month to eighteen years, and fifty per cent. of these occurred between the ninth and fifteenth years. An alcoholic history had been obtained in less than twenty per cent. of the recorded cases. In a few of these the amount of alcohol taken daily for a considerable period of time had exceeded a pint of brandy, but in most of them only a small quantity of spirits had been drunk. While the influence of alcohol in the production of cirrhosis in children was decisive, it was not so consequential as in the adult. Syphilis was mentioned as an etiological factor in about ten per cent. of the cases, tuberculosis frequently, acute infectious diseases seemed only accidentally in the history, chronic sepsis occasionally, and Thompson had collected a number of instances of obliteration of the bile ducts in the new-born, which were followed by cirrhosis.

Dr. Walls then discussed at length the symptomatology, the diagnosis, prognosis, and treatment of cirrhosis of the liver in childhood. Treatment, he said, had thus far been fruitless. Could the advent of the cirrhosis be anticipated, one might hope for much by withdrawing all harmful factors and giving careful attention to the hygiene and diet. Much had been claimed, particularly by the French school, for an exclusive milk diet, even if the cirrhosis be established. The use of the so-called resorbent waters, such as Carlsbad, the inunctions of gray salve, and the rational fulfilment of the symptomatic indications grasped the present possibility.

### Pericarditic Pseudocirrhosis of the Liver.

DR. JAMES B. HERRICK read a paper on this subject, which clinically presents relatively slight edema of the lower extremities, enlarged liver and rather obscure cardiac findings. Three cases described in 1896 by Pick showed postmortem an adhesive obliterating pericarditis; adhesive pleuritis and changes in the liver described as nutmeg liver, cirrhosis of the liver and coarsely granular liver. From his studies of these cases and other similar ones reported by other observers, he concluded that this symptom-complex resembling true cirrhosis was caused by a late pericarditis that induced circulatory disturbances in the liver, leading to an increase of connective tissue, in this way producing portal stasis and ascites.

Dr. Herrick referred to the importance, from a diagnostic standpoint, of inquiring into the past history for symptoms suggestive of preceding pleurisy for pericarditis; and of seeking the physical signs of active, or healed pleurisy. The coarser signs of pericardio-mediastinitis should be sought, such as the systolic retraction interspaces, the diastolic rebound, the paradoxical pulse, the fulness of the veins in the neck, and the feeble apex impulse.

Dr. Herrick agreed with Strumpell that the cases were not all of one pattern and thought that the trouble, perhaps, originating in the pericardium, might from this point involve the contiguous pleura and peritoneum; in other words, that passive congestion of the liver was not an ample explanation for all the phenomena of the disease. While Pick's observations had been preceded by somewhat similar observations of others, and while one might criticise somewhat his line of reasoning, yet full credit must be given to Pick for having most accurately described the symptom-complex, and for calling the attention of the profession to this peculiar condition.

### Medical Treatment of Cirrhosis of the Liver.

DR. JOHN A. ROBISON said that cirrhosis of the liver was incurable if the fibroid stage had supervened. Prior to this stage there was a small chance for recovery, especially in the syphilitic cases.

The medical treatment should be considered, therefore, under three headings: Prophylaxis, the first stage of treatment, and the palliative treatment. The knowledge of a gouty ancestry, especially with a list of deaths from cirrhosis of the liver, should be of great value to the patient in conducting his habits of life in a channel where toxic products would not produce the cirrhosis. But unfortunately for the cirrhotic victims, their medical adviser's advice was seldom asked, and less often followed, until active signs of the disease were present.

If the use of alcoholics be the cause of the disease, it should be stopped. If malaria or syphilis, the proper active treatment should be established. If the cirrhosis was manifestly the result of disease of other organs, treatment should be specifically directed toward them.

No matter what the etiological factor, the general management of the patient, the supervision of his daily habits, exercise, diet, and the treatment of the various symptoms must receive constant attention. The diet should be plain and simple, free from alcoholics, strong condiments, or spices, relishes, sauces, fried food, pastry, and sweets. Vegetables and fruits might be allowed, and milk should be a main staple. The patient should receive plenty of rest and fresh air. An outdoor life is beneficial, especially at mineral spring resorts and in mild climates.

Vomiting should be allayed by bismuth and alkalies, with the addition of thymol, resorcin, creosote, etc., if fermentative dyspepsia is present. The only benefit from mercurials seems to be in their action on the intestinal tract. The routine treatment of ascites by hydragogue cathartics, diuretics, and other drugs was unsatisfactory, and paracentesis should be resorted to early. The union of the liver to the abdominal wall with omentopexy would relieve the portal circulation before the ascites was established. Paracentesis should be performed early, and often, if the fluid rapidly accumulated, as the pressure embarrassed respiration and the heart's action. Opium, absolute rest and the withholding of food from the stomach were essential in the treatment of hematemesis.

In case the diarrhea was intractable, large doses of the bismuth compounds were the safest remedies. In many cases it could not be checked, and it would be necessary to support the patient by administering the concentrated foods and alcoholics. Exhaustion should be combated by the use of tonics and restorative remedies.

DR. I. A. ABT presented a case of hypertrophic cirrhosis of the liver in a Russian boy, 13 years of age, whom he had had under observation for six years.

DR. HENRY B. FAVILL referred to mediastinal pericardial cirrhosis and narrated a case, twelve years of age. He said that the case presented by Dr. Abt and the paper by Dr. Walls would lead to the idea that these were all infections. If there was

anything more pronounced than another in connection with the subject of cirrhosis of the liver, it was the growing belief that it is infectious either primarily or is the result of infection, and whether the suggestion of Adami (as to the presence of latent and changed micro-organisms in the liver, which become weakened under toxic influences and stimulants) be accepted, or whether another view is taken of the infection, the general trend of opinion on the subject is that instead of having essentially a degenerative fibrosis, as an explanation of the cirrhotic process, we have a complex process in the fibrosis which bears some essential relation to the infective agent directly, causing it to be whipped into renewed activity by pre-existing toxic agents.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, XIV.

(Continued from page 474.)

#### Administration of Medicine per Os.

Medicines may be given by the mouth in the form of a capsule, powder, cachet or liquid. When capsules are given the amount of the combined ingredients should be observed so that the capsule will not be too large for the patient to swallow. If such be the case, the druggist may be instructed to make up double the number of capsules and direct the patient to take two at each dose. Capsules can be prescribed for certain patients who object to the taste of medicine, especially when it is given in sufficiently small doses. Creosote may be taken in capsules rather than in an unpalatable mixture. There are, however, instances where capsules have traversed the entire gastro-intestinal tract undissolved; under such circumstances a powder or liquid may be prescribed.

Powders are preferable to capsules when large doses are to be given and when the preparation is palatable. Sulphonal serves as an illustration, since it is given in two large doses for a capsule and acts more promptly when dissolved in hot water. There are certain drugs which should never be prescribed in powder form, because of their tendency to deliquesce. Salol and sodium salicylate belong to this class. Some combinations in the form of a powder, liquefy, as is demonstrated by combining chloral and camphor.

The liquid preparations can be prescribed suitably in the majority of cases if the practitioner observes care in selecting a proper vehicle. As previously mentioned, medicines which tend to irritate the stomach should, if possible, be taken immediately after eating, and well diluted in water. Arsenic when given in the form of Fowler's solution to children afflicted with chorea, should always be well diluted. The nurse should be instructed to put the required number of drops in at least half a glass or a glass of water, and if the child can not drink it all at one time, set the glass aside for a few minutes and then let him drink the remaining portion. In this way the stomach can be made to tolerate much larger doses than when given in too concentrated form. Iodids should likewise be well diluted before being introduced into the stomach if large doses are in the end desired.

In acute cases where changes in the condition of the patient may quickly arise, small amounts should be prescribed at a time; if capsules are given the physician should not write, as a rule, for more than fifteen, or two ounces if liquids, unless more than one teaspoonful is given at a dose. The patients feel that they are being imposed upon when they are required to purchase new medicine if one or two ounces of the previous prescription remains unused. On the other hand, in chronic cases it is preferable to prescribe much larger quantities at a time.

In administering certain medicines by the mouth it should be remembered that the mucous membranes of the stomach and intestine may not be in condition to carry on proper absorption. Literature records several cases where some opiate preparation has been introduced into the stomach to relieve severe localized pain or headache, and resulted in acute opium poisoning; this was not because the dose was too large but the gastro-intestinal tract was not in condition to absorb the first doses given; consequently by this delayed action, several doses were taken up at the same time with fatal result.

A word also must be said as to caution in prescribing for pregnant women. There are some drugs which produce untoward results upon a pregnant uterus by exciting abnormal contractions, and perhaps causing abortion. Ergot and quinin are especially included in this class; they act upon the unstriated muscle of that organ and set up a tendency to the expulsion of its contents.

There is danger in placing in a patient's hands a prescription for certain drugs, such as morphin, cocain, chloral, etc. If the physician finds it necessary to prescribe these drugs to susceptible individuals he should not neglect in some way to indicate to the druggist that they should not be refilled without his knowledge and consent. Otherwise he has not done his duty toward that patient. Another point is that such patients are prone to talk to their neighbors and advise them to try their medicines for relieving symptoms apparently similar to their own, while in fact the cause may be far different. A writer states one such instance where a female patient was given pills of hydragryri protoiodidum to cure a headache of specific origin; the results were so miraculous and satisfactory that in a short time several of her lady friends were taking the same little yellow pills upon her recommendation. This bears out the old rule that what is food for one may be poison for another.

(To be continued.)

#### As an Inhalant in Bronchitis.

|                              |      |    |    |
|------------------------------|------|----|----|
| R. Tinct. benzoin comp. .... | 3ii  | 7  | 50 |
| Tinct. toluani ....          | 3ii  | 7  | 50 |
| Spts. chloroformi ....       | m. x |    | 66 |
| Spts. etheris ....           | m. x |    | 66 |
| Spts. ammon. arom. ....      | 3i   | 3  | 75 |
| Alcoholis ....               | 5v   | 18 | 75 |

M. Sig.: Use in the inhaler three or four times daily.

#### Ichthyol in Trachoma.

Ichthyol, according to *Rec. de Thér.*, has been employed in the treatment of trachoma. It is used in the form of instillations as follows:

|                            |     |    |    |
|----------------------------|-----|----|----|
| R. Ichthyol ....           | 3ii | 7  | 50 |
| Glycerin ....              | 3ss | 15 |    |
| Aque destil q. s. ad. .... | 3ii | 60 |    |

M. Sig.: Drop into the eye once or twice daily, first anesthetizing the conjunctiva with cocain.

Under this treatment diffuse infiltrations of the conjunctiva in trachoma, of not very long duration, disappeared in a week's time; the follicles diminished in size and no new ones were formed. In chronic cases the purulent secretion was arrested with rapidity. It is also efficacious in corneal pannus.

#### Methylene Blue in Otitis Media.

According to H. Gaudier, in *Lac. Sem. Méd.*, the installation of a warm solution of methylene blue, 2 per cent. strength, into the auditory canal is of great service in the treatment of certain chronic forms of otitis media, especially in fetid otorrhea of children. He employs the following method: First thoroughly cleanse the canal with a warm soap and water injection, then instill 15 to 20 drops of the methylene solution into the ear. During this procedure the patient is directed to make forced expiratory movements while keeping the nose and mouth closed. In this way air is forced into the ear and the solution passes from the canal into the tympanic cavity. He states that the deodorizing properties of the methylene blue render it superior to other antiseptics. In using this prepara-

tion a pure medicinal article must be insisted on as some similar preparations contain arsenic and zinc.

#### Treatment of Acne Rosacea.

According to Dr. J. Nevins Hyde, a systemic treatment that will apply to any case can not be outlined. The treatment is that of the patient rather than of the disease. The use of wines, beers and liquors of all sorts should be interdicted. The diet should be simple in character; tea and coffee should be restricted, and all articles of food selected with special care. Proper attention should in all cases be given to the gastrointestinal tract as dyspepsia and constipation are effective factors. Dr. Hyde states that most drugs are valueless aside from the local treatment. The local treatment of the first grade of acne rosacea should consist of stimulating lotions of green soap, formalin or sulphur in connection with ablutions of hot water. The following is recommended:

|  |       |    |    |
|--|-------|----|----|
| R. Sulphur. precip. ....                                   | 3i    | 3  | 75 |
| Pulv. camphoræ ....  | gr. v |    | 30 |
| Pulv. tragacanth. ....                                     | gr. x |    | 66 |
| Aque calcis  |       |    |    |
| Aque rosæ, āā.....   | 3i    | 30 |    |
| M. Ft. lotio. Sig.: Apply locally several times daily; or: |       |    |    |
| R. Sulphuris precip. ....                                  | 3i    | 3  | 75 |
| Ung. aque rosæ .....                                       | 3i    | 30 |    |

M. Ft. unguentum. Sig.: Bathe the parts well in warm water and apply locally twice a day.

### Medicolegal.

#### Number of Physicians Allowed on Boards of Health.—

The Supreme Court of Louisiana says, in the case of *State vs. Kohnke*, that there is no sufficient reason for holding that the general assembly, in requiring, by Act. No. 192 of 1898, that three out of five members of municipal boards of health "shall, if practicable, be duly licensed and registered physicians," intended to prohibit the organization of any municipal boards with more than three physicians as members. The purpose seems, rather, it says, to be to require that a majority of the members shall be physicians, leaving the selection of the others to the discretion of the municipal councils, though, no doubt, this purpose is more plainly expressed in the provisions in the act relating to the parish boards.

**Duty of Secretary of State Board of Health.**—The case of *McClatchy vs. Matthews* was an application for a writ of mandamus to compel the secretary of the State Board of Health of California to permit the publishers of a local newspaper to inspect and take copies of the written reports of a bacteriologic examination of an alleged case of bubonic plague made for the State Board of Health. But from the answer filed it appeared that the secretary did not have the care, custody, or control of the reports in question when this proceeding was commenced; that they had prior to that date been transmitted to the governor, as a special report of the State Board of Health. In other words, the reports had been made to the State Board of Health, and by its direction transmitted to the governor. The secretary was only one member of the board, and, as its secretary, it was his duty, the Supreme Court of California says, to comply with all the lawful directions that it might make in the conduct of its business. Whether he opposed their transmission or consented thereto was immaterial. It could not be said that he committed any wrong in complying with the directions of the board; nor could it be said that it was unlawful, under the circumstances, for the board to transmit the reports to the governor. This point the court considers decisive of the case, and, in consequence, it reverses a judgment granting a peremptory writ of mandate as prayed.

**Failure of City to Warn Employee as to Smallpox.**—The case of *Nicholson vs. City of Detroit* was brought to recover for the death from smallpox of a carpenter who was in the employ of the city. At the time he contracted the disease he was at work upon a new hospital near an old one for contagious diseases—particularly smallpox; or was employed in tearing down the old building. Concerning the case, the

Supreme Court of Michigan says that it was a cruel thing to permit him to enter the valley of the shadow of death unwarned, if those who sent him knew of the danger. A case involving a stronger appeal to the sympathy of a tribunal could hardly be imagined. But the court feels constrained to say that, if there was culpable negligence here, the remedy was limited to the persons to whose negligence the deplorable event was due, if there was a remedy. It was not a case where the doctrines of imputed negligence and that the principal must answer could be applied. The court says that it has been held that a city was not liable to a non-paying patient for injuries resulting from the neglect or misconduct of hospital officers or servants; or for the unskilful treatment of a resident physician; or for failure to take proper precautions to prevent the spread of the smallpox; or to notify the party suing, who was required to assist in the removal of the corpse of a person who had died of this disease, of the dangerous nature of the service required; or where a person caught the smallpox from a nurse who was permitted to leave the hospital without being properly disinfecting; or for carrying a well person to the smallpox hospital, whereby he contracted the disease; or for negligence of a servant of the board of health in removing garbage. The true theory, the court holds, is that the township or city represents the state in taking measures for the preservation of the public health and building hospitals for contagious diseases, and, like the state, it enjoys immunity in case of injury to individuals, leaving liability for such injuries to rest upon the persons whose misconduct or negligence is the immediate cause of the damage. The township and city must always act through officers. If it provides a smallpox hospital, it must do it through persons selected for the purpose; and whether the law broadly directs that it shall do a thing, or shall select officers whose duties are prescribed by law, its obligation is the same. In imparting a portion of its powers, the state also imparts its own immunity.

**The Law of Insanity.**—The Supreme Court of Nebraska makes a kind of summary, in the case of *Clarke vs. Irwin*, of the law of insanity as applied by the courts of this country. An examination of the reported cases, it says, shows that the issue of insanity most frequently occurs in judicial proceedings as follows: First, in direct proceedings to procure the commitment of persons alleged to be insane; second, in suits affecting the validity of wills, where it is sought to show that the testator was not of disposing capacity; third, in criminal proceedings, where the defense pleaded is insanity and irresponsibility; fourth, in suits to avoid contracts because of insanity; and, fifth, in proceedings otherwise barred, where the plea is that he against whom the statute of limitations is pleaded comes within the enumerated exceptions because of insanity. The rule deducible from these cases is that for the purposes of judicial inquiry men are either sane or insane, and that such insanity is either total or partial. A total deprivation of sense, without lucid intervals, presents few legal difficulties. Such an unfortunate may be presumed never to be on an equality with the sane. The law, however, distinctly recognizes that species of insanity where the subject is deprived of his reason but a portion of the time, or deprived of his reason, either temporarily or permanently, only upon certain subjects. Instances of this character are not rare. They constitute the major portion, if not all, of the reported cases. Early in the history of English jurisprudence the courts did not make a distinction between different degrees of insanity. Insanity was regarded as a fixed term in law, having a certain meaning. If a man were insane on one subject, he was supposed to be insane on all subjects, and for all purposes. Continuing, the court says that in suits to avoid contracts and conveyances on the ground of insanity, it is settled law that the insanity must have entered into and induced the conveyance or contract; in other words, that it was not the act of the free and untrammelled mind, and that on account of the diseased condition of the mind the person entered into a contract or made a conveyance which he would not have made had he been in the possession of his reason. In the case of wills in most all jurisdictions it is held that the insanity available for the purpose of invalidating the will must be of a kind and degree that clearly

affected the testator's disposition of his property, so that the disposition attempted to be made can not be said to have been that of the testator, but the result of mental disease. In criminal proceedings, where the defense is insanity, the universally recognized rule is that, before the defendant can escape punishment, it must appear that the insanity induced the commission of the crime, and that the defendant, because of the diseased condition of his mind, could not understand the consequences or moral enormity of the act, or had not the power of resisting the impulse to commit the crime. And the court holds here that there is no valid reason why the rule regarding monomania or partial insanity should not be applied in the determination of questions involving the statute of limitations.

1. Typhoid Fever.—From a general study of typhoid fever Wasdin has come to believe that the treatment of the disease should be directed more energetically to the destruction or attenuation of the germ in what he considers its primary pneumonic colony, not lessening, however, the great importance of the destruction of the secondary intestinal or terminal colonies. He has sought those germicides that will not be injurious to the patient and will be effective, and this he has found in the chemical recently described by Novy, benzylacetyl peroxid, which is germicidal in aqueous solution, 1 to 33,000, being equivalent to 1 to 1000 bichlorid solution. He has found this innocuous in his patients when given by the mouth or hypodermically in the abdominal cavity after laparotomy and in powders of 3 decigrams three times a day for an indefinite time. It is rapidly eliminated as a hippuric acid by the kidneys. Novy will soon give fuller details. Wasdin has found its application in typhoid fever to have very happy results, and its use has been directed to decrease the germs in the primary lung colony and also in its secondary intestinal colony, and it has been used by hypodermoclysis to combat terminal expressions with the result that in 24 cases the disease has been limited almost entirely to the expression of intoxication from its primary focus, the intestinal symptoms being entirely in abeyance. He suggests the importance of the danger of laying

of dust in the streets by polluted water, and suggests that it would be safer perhaps to filter the street-sprinkling supply and allow the drinking of hydrant water.

**4. Phlegmon and Fistula of the Lower Jaw.**—Manley summarizes his article as follows: Perforative endostitis of the lower jaw is an infective lesion usually consecutive to caries of the crown, incomplete extraction, or the late eruption of the third molar. Infection first provokes an alveolar abscess, with widespread tumefaction and rigidity of the jaw. This may be followed by dislodgment of the imbedded fang or by alveolar necrosis. Perforative osteitis from a dead fang occurs through the least vascular surface of the mandible, by way of the dental canal; this is followed by an abscess, ultimately degenerating into a chronic, unsightly fistula. Surgical aid is resorted to, rather as a means of removing the blemish than because of severe pain. Operative intervention embraces the complete extraction of diseased fangs; dissection away of scar tissue; the thorough curettage of the sinus, and the closing of the breach in the soft parts in such a manner that little or no deformity will result after healing. Drainage must be entirely from the base of the alveolus into the mouth, hence the importance of frequent cleansing of the gums with antiseptic lotions until repair is complete.

**5. Peripheral Anesthesia Paralysis.**—A study of three cases reported by Levings shows that the muscles most frequently implicated are those supplied by the musculocutaneous, circumflex, musculospiral and median nerves. Few of these could be injured in the axilla by stretching, but all can be injured in the neck or between the first rib and the clavicle by pressure, and the lesson to be learned is that during operative procedure the arms should never be forcibly abducted or extended and maintained in this position for any considerable time. Forceful extension or abduction of the arm for the purpose of practicing artificial respiration or while clearing out the axilla in carcinoma, or other operative measures about the shoulders for short periods of time, is not followed by paralysis.

**8. Cirrhosis of the Liver.**—The treatment of hepatic cirrhosis by the Talma-Morison operation is discussed by Brewer, who reports 5 cases and analyzes in tabular form about 50 more from the literature. From reviewing these statistics he finds at least 6 patients who have been cured of ascites by this procedure, and who have remained well for two years or more; 6 others have died, with relief of this symptom from 2 to 6 months before death, or had not been under observation long enough to demonstrate a permanent cure. Another patient suffering from hemorrhage of the alimentary canal was promptly cured by this operation. Many others have been materially benefited. Thirty-eight have recovered from the operation, and considering that the great majority of these were within a few weeks of inevitable death, he thinks that it should encourage us to suggest operation at an earlier and more favorable stage of the disease. If this suggestion is followed he believes that statistics will show a great improvement over those he is able at this time to present.

**9. Etiology of Hepatic Cirrhosis.**—According to Crook there are only three forms of hepatic cirrhosis that have gained an unequivocal position in medical terminology. Venous atrophic cirrhosis, the original cirrhosis of Laennec, is by far the most common form and the only one recognized by many writers. He analyzes the cases reported by the New York Health Board for 11 years, nearly 5000 in number, and finds that the largest number of cases occurred between the 25th and 45th years. It is rare in youth and infancy and in old age. There are 9 cases, however, reported under one year of age, which disposes apparently of the doubt of the existence of the disease in infancy. The great majority were males, 62.28 per cent., and nearly three-fourths were of foreign birth. This goes to show that the native American is much less liable to the condition; while of the foreigners the Irish furnish the larger proportion; the Germans are a short distance behind. Among the exciting causes, alcoholic stimulants take first rank, and even the milder alcoholic beverages are not innocuous in this direction. According to Lancereaux, *vin ordinaire* is a

common cause in France. Syphilis has been credited with an important influence, but the difficulty of obtaining information makes reliable statistics scarce. No doubt in some cases it is combined with alcoholic excess. Other conditions mentioned are malaria, infectious diseases such as typhoid, over-eating of highly spiced foods, certain mineral poisons, etc. According to Von Kahlen, cases of acute yellow atrophy of the liver may also indirectly produce cirrhosis. Other forms mentioned are the hepatic cirrhosis of Hanot, where the liver is uniformly large and smooth, moderately granular on the surface, differing from the ordinary venous cirrhosis in the tendency of the liver to remain enlarged, probably having the same etiologic factors, though occurring rather earlier in life, and biliary cirrhosis which consists fundamentally in a primary affection of the biliary reticulum, more especially in an angiocholitis or a peri-angiocholitis of the bile-ducts of small and medium caliber. Here it seems highly probable, he says, that the immediate cause of the trouble is an upward extension of some pathogenic influence through the biliary system.

**10. Treatment of Alcoholic Cirrhosis.**—The logical indications, according to Converse, are the suppression of alcohol, a non-irritating and a minimum toxic diet, chiefly milk, until the gastro-intestinal symptoms and congestion have subsided and gradually changing to eggs, vegetables, etc., and, last of all, meat. Purgatives and laxatives should be given judiciously at intervals. The patient should take advantage of rest, open air, moderate hydrotherapy, and lead as careful a life as his financial situation and occupation will permit. When ascites develops, it is all important to differentiate between the atrophic and the hypertrophic forms, but the treatment should be mainly on the same lines. If accumulation is due to mechanical obstruction in the portal system, frequent tapplings will probably only precipitate the end.

**11. Diagnosis of Hepatic Cirrhosis.**—The following are the conclusions of Wilson's article: 1. The term cirrhosis is an unfortunate one. It has been applied to conditions wholly unlike etiologically, anatomically and clinically, which have, however, in common an overgrowth of the connective tissue of the liver. 2. The term chronic interstitial hepatitis is to be preferred. 3. Alcohol is by far the most common cause of interstitial hepatitis alike in the cases in which the liver is of normal size or slightly enlarged, in the atrophic form and in the hypertrophic form. 4. The symptoms of this condition are in many cases ill-defined and not rarely the liver is not changed in size or contour. The clinical diagnosis in a large proportion of the cases is therefore impossible. 5. In the presence of definite symptoms and of the signs of enlargement or diminution of the liver, that is to say, in terminal conditions, the diagnosis is commonly a simple matter.

**12. Infantile Cirrhosis.**—According to Hollopeter, who reports two cases, cirrhosis of the liver in infants and adolescents is not so infrequent as clinicians infer and cirrhosis in children can generally be relegated to either syphilitic or alcoholic types, with a very small percentage as sequelæ of the acute infectious diseases. As a rule the premonitory symptoms are disguised by a long train of gastro-intestinal irritations that render early diagnosis uncertain.

**13. Intestinal Obstruction from Gallstones.**—Pileher reports a case, and considers the symptoms and diagnosis. It is not unusual, as in the case reported, for notable abdominal symptoms to be entirely absent. The diagnosis does not usually declare itself until the lower portion of the small intestine is reached, which he considers as probably due to localized irritation and circumscribed peritonitis, with its attendant paresis, probable adhesions and possible acute angulation. The diagnosis must often be obscure. He suggests exploratory operation, holding that while in many cases it may be fruitless and that some cases may be operated on which might have recovered if left alone; nevertheless the operative failures will bear but an insignificant relation to the increased number of recoveries of patients who otherwise would have died.

16.—See abstract in THE JOURNAL, xxxvi, p. 1650.

17.—Ibid., xxxvii, p. 1481.

18.—*Ibid.*, p. 1480.

19.—This article has appeared elsewhere. See THE JOURNAL of January 4, title 50, p. 61.

20. **Tuberculosis.**—Fanoni takes an extreme view in regard to the danger of contagion or infection from consumption and would restrict the marriages of consumptives. He insists on early diagnosis and reporting of cases and the isolation of patients. He is sanguine enough to say that a battle waged in this manner against consumption would stamp out the disease in a few years.

24. **Dengue.**—Graham finds that dengue in Beyrouth, Syria, offers peculiar advantages for its study. He experimented with the mosquito and commenced a series of investigation quite analogous with those of Reed and Carroll to decide whether these insects carry the infection. Besides clinical observations which pointed strongly to this, he experimented by direct inoculation, infecting his mosquitoes from patients suffering from the disease and then placing them under nettings with healthy persons, who readily submitted to the experiment at a cheap rate and produced the disease with the entire exclusion of other insects. To further make his experiments conclusive he carried the mosquitoes out into the country villages where dengue was not to be found, and there made his inoculations. He thinks his experiments prove that dengue is not a contagious disease, but that certain forms of *Culex* may carry it from one person to another. Blood examinations carefully made revealed an ameboid form inhabiting the blood corpuscles which he has been able to study throughout the most of its life history in the blood. He illustrates this, and says it may not be absolutely proven that this hematozoon is the cause of dengue, but its constant presence in the red corpuscles during fever, its resemblance to the parasite of the Texas cattle plague, and its similarity in mode of growth and propagation to the malarial parasite all point in the same direction and lead us to believe by analogy, if in no other way, that in this parasite we have the cause of dengue.

25. **Yellow Fever.**—Souchon criticises the recommendations of Reed and Carroll as regards quarantine, quoting large numbers of cases which seem to him to prove that disinfection alone without quarantine is insufficient. He says that the final recommendations of Reed and Carroll that the disinfection of vessels before departure be thoroughly carried out, together with abolition of all causes of yellow fever in the ports, is the key to the situation. If this can be done quarantine regulations may be altered.

27. **Regenticides.**—Spitzka's article is an elaborate historical study of the mental conditions of assassins of prominent individuals. It covers an immense field and goes a long way to show that in comparatively few cases are these criminals to be considered insane.

28. **X-Ray in Brain Tumors.**—Mills reports a case and Pfahler discusses the x-ray diagnosis. The tumor was correctly located during life, but only a portion of it was removed. The patient died two hours after operation. The only previous case to the one reported is that of Church of Chicago, where a cerebellar tumor was diagnosed during life and found by autopsy where the skiagram showed it. Obici and Ballici have also showed the presence of tumor, but postmortem. Pfahler has experimented on living individuals and also cadavers with the x-ray to detect tumors, and from his experiments draws the following conclusions: 1. That fibrosarcomata, and probably other tumors, can be photographed in the living subject and their location and extent shown. 2. That various tumors can be photographed in their most common locations. 3. That other abnormalities and deficiencies in brain tissue itself can be photographed, which will probably be of value in the diagnosis of cysts, softening and hemorrhages. 4. That over-exposure of the third series and the under-exposure of the fourth show that good results will only follow the most careful technique and keen judgment as to the special conditions in each case. 5. That the shadows obtained in normal parts of the brains studied indicate that great care is necessary in the interpretation of any shadow obtained in the living subject.

30. **Tongue and Lip Centers.**—With the report of a case of cerebral bulbar palsy, Dana describes the localization of the tongue and lip centers, both in view of clinical experience as reported in the literature and from experiments observed. His conclusion is that in the human brain the lip and the tongue centers are closely connected and more or less identical. One group of centers for the tongue is in relation with the articulatory movements of the lips, and another with the movements of mastication, opening and shutting the mouth and deglutition. The area for the excitation of movements of the tongue is a wide one, being associated probably in its lower parts with the articulatory movements and in the upper parts with the masticatory movements. The centers lie at the base of the pre- and post-central convolutions. Paralysis of the tongue, and to some extent of the lips, from a one-sided cortical lesion occurs, and may perhaps be explained by the fact that in many individuals the brain becomes accustomed to use only the center of one side, and that temporary paralysis will frequently follow an injury to the center in use. This will also explain the difficulties of deglutition and often of articulation in hemiplegia. Dana also doubts that permanent bulbar paralysis can be produced by cortical lesion of one hemisphere, if so, it must be considered an anomaly.

31. **Myasthenia Gravis.**—Sinkler describes the disease, having studied all the reported cases. He describes its essential features, which are weakness beginning in the bulbar muscles—those of the tongue, lips, larynx and eye—with exhaustion and apparent recovery after rest, lack of sensory symptoms and the myasthenic reaction, that is, exhaustion by prolonged faradic stimulation as from voluntary effort, but no exhaustion by galvanism. The etiology is also discussed. It seems to occur alike in both sexes, and frequently follows some acute illness. There may be a family tendency to neuroses, but there is no constant predisposing cause. Ptosis is one of the most common symptoms, occurring perhaps only in the latter part of the day. Other symptoms are ocular muscle weakness, difficulty in deglutition and articulation, weakness, especially in the neck, and dorsal movements, and sometimes facial paralysis—all aggravated by various conditions such as cold weather, menstruation and general affections—normal reflex and absence of Babinski reflex. In most cases no postmortem lesions were discovered; rarely degeneration existed in the medulla; there was nothing to settle the pathology. The most reasonable theory is that there is some toxin attacking the motor neurons, but we are ignorant of the character of the toxemia. The well-marked cases are easily diagnosed; bulbar paralysis is readily distinguished by the ptosis and distribution of the lesions throughout the organism, the less progressive character and the absence of sensory disorders when the limbs are involved. The organic symptoms show up clearly from hysteria and neurasthenia. Nearly 50 per cent. of the cases end fatally. The disease ranges in duration from a few days to many years. It is difficult to say whether complete recovery ever occurs. No treatment seems available, strychnia is useless, and electricity is likely to do more harm than good. Arsenic has apparently been of service in some diseases, but its specific action is questionable. The best line of treatment is building up the general health, improving nutrition, avoiding exposure and carefully regulating the exercise. In fact, the treatment is much like what would be employed in marked neurasthenia.

32. **Scleroderma and Sclerodactylia.**—These conditions are discussed and cases reported by Sachs, who calls attention to the resemblance in effect of treatment between this condition and myxedema, thyroid gland having remarkably good effects in both. He calls attention to the typical facies of the disease, the pinched and attenuated nose, sunken cheeks, and retraction of the upper lip in advanced stages. As regards thyroid he does not say that it does good in all cases, but that it is well to try it. Everything else has been tried without much benefit, and this seems to be the most hopeful medication.

33. **Hypochondria.**—Dereum describes the symptoms and differentiates hypochondria from hysteria, neurasthenia, etc. He also calls attention to the necessity of carefully distinguish-

ing between the condition itself and the various hypochondriacal stages observed in some insanities. Simple or true hypochondria is a well-defined affection, he says, which may last for an entire lifetime. It may be general in its type, or specialized on a few functions on which the attention of the patient is fixed, as in the gastro-intestinal or sexual form. It may appear early in childhood.

**36. Sensory Area of the Umbilicus.**—Spiller reviews the subject and reports a case. He concludes from his study: 1. That Head is probably correct in placing the umbilicus between the ninth and tenth thoracic sensory areas. 2. That the Babinski reflex may be absent in cases of lesion of the lumbar and sacral regions of the cord, though the clinical symptoms may indicate merely that the cord is compressed above the lumbar region. The absence of the Babinski reflex in such cases may possibly be a valuable sign of disorganization of the lumbar and sacral regions. 3. That while loss of the patellar reflexes may occur from transverse lesions of the cord above the lumbar region, the cause of this loss in a certain number of cases is to be found in lesions of the area through which the reflex arc passes.

**37. Nervous Syphilis.**—Collins points out the difference between parasyphilitic and syphilitic conditions, holding that the latter are not amenable to antisypilitic medication. He gives mercury or iodine for other indications, and in cases where tabes and paresis occur within a comparatively short period after the infection and proper antisypilitic treatment has not been employed, he would employ it. He recognizes syphilitic pseudo-tabes and syphilitic pseudo-paresis. As regards the recovery from syphilis he is dubious, and does not agree with syphilographers who teach the rapid and complete curability of syphilis. There is nothing that will absolutely insure a syphilitic of perfect safety in the future. He also says that the time to begin antisypilitic medication is when the diagnosis is made. Unfortunately we must often wait for this. His method of using mercury is preferably by inunctions and next hypodermically, rarely by the mouth or inhalation. No definite dose can be given, each case requiring individual treatment. The patient should never realize the toxic effects of the drug. The maintenance of nutrition and the general tone of the patient are insisted upon. In treating syphilitic nervous disease mercury should be given first, in exudative nervous syphilis, while the iodids should be given preferably when the nature of the nerve lesion is that of granuloma. The dose of iodid must be regulated by the individual case and the duration of the treatment will depend on the readiness with which the patient responds. The general treatment is that for a patient suffering from depressing neurasthenia. The special treatment applicable to each case will depend upon the intensity and seat of the lesion.

**40. Tuberculosis.**—Viotor deprecates the prominent emphasis on the contagion of tuberculosis as an error in fact as well as judgment, and as liable to create a condition of panic which does infinite harm and does nothing toward combating the disease. A large proportion of the community has tuberculosis and every little symptom is magnified by public fear. The problem is a dual one. Tuberculosis is a diseased condition caused by germs of low vitality which die rapidly under unfavorable conditions, but its diminution by attacking it outside the living body is impossible because of its strong entrenchment in the bodies of people in the condition of lowered vitality. As long as such people exist, its virulence can never be destroyed. The great sources of such lowered vitality are insufficient food, insufficient air and light, overwork and worry. From this it follows that the fundamental factor in the existence and increase of tuberculosis is the health of the mass of the people, and that the community which does not vigorously attack the removable causes that lower this mass-health, passively supports a city laboratory for the manufacture and maintenance of virulent cultures of tubercle bacilli. The only definite decrease in tuberculosis is such as that recorded: 1. in the cures effected in patients who adopt some modification of the open-air life, with superfeeding and freedom from overwork

and worry; 2, the improvement in certain New England statistics, the only changed factor of general extent being the almost universal use of the bicycle and other reactions tending to increase outdoor life, especially among women; 3, the decreasing statistics of tuberculosis in a German village where tuberculosis sanatoria were established, the lives of the villagers consciously and unconsciously imitating the good example of the sanatoria. She suggests the following: An unpaid municipal tuberculosis committee of men and women fitted to view the subject broadly. Sub-committees on air and light in tenements and dwellings; in other buildings, as workshops, factories, schools, etc.; on cooking and savory serving of food on large enough scale to give the poorest a chance to be well nourished; on employment, to put the vast army of unemployed or precariously employed in connection with the equally vast field of undone work; on dust and noise, which decrease the available air and light in even the best localities; on nursing and disinfection and so on, and a modern sanatorium located in each section of the city as a living example of the method of living which cures. To these sanatoria selected cases should be sent for short periods to learn the lesson by actual experience; returning to their homes they will themselves be teachers to ever new and widening groups. Finally, but of least importance for the eradication of disease, a distinctly charitable hospital is needed to care for the really destitute and desolate; but with the proper better control of the situation by the whole community, this hospital will not need to be a very large one.

**41. Cleft Palate.**—The following points are mentioned by Porter as of importance in the technique of the operation for cleft palate; 1. Careful and complete denudation of the whole cleft, best accomplished by grasping the tip of the uvula with fine forceps, and cutting from before backwards, on either side, a continuous strip of mucous membrane about one-eighth of an inch in width. If, as sometimes occurs, the edge appears too thin, the flap may be split for one-eighth of an inch before suture, thus giving a broader surface for approximation. Two lateral incisions are then made from the level of the canine teeth, close to the margin of the alveolar arch, back to, and through the fan-like expansion of the tensor palati muscle. Each incision should not be nearer than one-half an inch to the tendon of this muscle where it winds around the hamular process. By these incisions, tension on the stitches through the soft palate is avoided, and after healing the tensor again resumes some of its functions. The levator palati muscle should not be cut and the enlarged tonsils and adhesions should be removed previous to the operation. The most important points are that the edges to be sutured should never be crushed by grasping with forceps and that all tension must be avoided. As a rule too many stitches are used and they are tied too tightly, causing subsequent swelling and cutting out. He puts the suture stitches three-eighths of an inch apart and some distance from the edge of the wound. Usually 6 will suffice. He has used silk previously soaked in balsam of Peru which is better than silver wire or silkworm gut. Rose's position is, without question, superior to any other, and unless contra-indicated, the anesthesia should be chloroform, as allowing more quiet breathing and the absence of mucus. The after-treatment he thinks has been too much neglected. Adhesions about the palate should be divided where present, the soft palate exercised, massaged and made movable by voluntary contraction in adult cases, and by passive motion and stretching with the finger, in children. The power of speaking properly, in spite of good technical results, is always in direct ratio with the time spent in instruction and intelligent effort of the patient. It is possible that enlarged tonsils and adenoids may in certain cases aid in closing the nasopharynx and be of definite advantage in speech. Porter suggests that possibly the submucous injection of paraffin according to Gersuny's method, may be of advantage to diminish the nasopharyngeal space at a point opposite the soft palate.

**42. Mechanical Appliances in Soft Palate.**—Raymond has never seen a case where perfect speech has resulted from the surgical treatment of cleft palate alone. Any careful operator can close the palate and make it a surgical success, but he

never found anything like a physiologic success; hence the failure to produce speech. He therefore believes in appliances fitted and adapted so that even children can become accustomed to them and wear them with as much ease and comfort as a set of artificial teeth and which would be a great help to perfect articulation. He reports a number of cases demonstrating this point.

**45. Treatment of Tuberculosis.**—Dixon believes in the climatic treatment of tuberculosis, but says only general rules can be employed in advising locations. Only trial will show which special place will most benefit a given case. Patients in the infiltrative stage with good hearts, a fair amount of strength, and without nervous manifestations or high temperature, should be sent to high altitudes; but it is usually wise first to send them to a moderate altitude. The more advanced cases should be sent to medium altitudes, and still further advanced cases to a still lower altitude. The two essentials of a good climate for the treatment of tuberculosis are dryness and sunshine.

**46.**—See proceedings of the Cincinnati Academy elsewhere in this issue.

**48. Strangulated Hernia.**—After general remarks and report of a case, McGaughey summarizes as follows: "1. Every irreducible hernia is a menace to the patient, and it is the duty of his medical adviser to fully explain the possible dangers and to recommend interference. 2. Strangulated hernia should not be subjected to violent or prolonged attempts at reduction, but operation should be resorted to as soon as possible after reasonable attempts to replace it have failed. 3. The sac should be opened in every case. 4. The omentum should be tied securely, and cut off well above the point of constriction. 5. Lavage of the stomach should be made use of prior to the administration of the anesthetic if there has been stercoraceous vomiting. 6. No case not actually moribund should be refused operation."

**59. Ulcero-Membranous Angina.**—Mayer reports a case of ulcero-membranous angina in which numerous bacilli and spirochetæ were discovered, corresponding with those described by Bernheim and Vincent. He reviews what he knows in regard to the disease, giving its nomenclature by various authorities and suggests that it is generally conceded that the presence of virulent bacilli precludes the existence of the diphtheria germ. The symptoms are comparatively insignificant in the beginning, and the prognosis is generally good, but there is a tendency to recurrence. Clinically it is very difficult to differentiate from any one form of specific disease, hence the importance of its careful study. It must be borne in mind that syphilis may be present. A membranous deposit with fusiform bacillus and spirillum may be associated with underlying syphilis. In this case he would say: Treat the angina and eliminate that, if necessary giving iodids until entirely healed. The treatment consists in the use of boric acid solution as a gargle and the local application of iodine and peroxid of hydrogen.

**61. Phrenic Nerve Injuries.**—Schroeder has studied a case of paralysis of the phrenic nerve and has also made experimental observations by pinching the nerve during exposure in tubercular gland operations, and also in animals. Green reviews at length the bearing of these experiments and others on the question of the innervation of the diaphragm. The general conclusions are summed up as follows: "1. From the clinical and experimental data it would seem that the diaphragm is not an essential muscle of respiration. 2. That as the symptoms commonly described as caused by an irritation of the phrenic were uniformly absent not only in the operation but in all of the experimental work as well, it is safe to infer that they may have been due to something other than a simple injury to the phrenic. 3. That while from an anatomic point of view the diaphragm undoubtedly is innervated by branches from the intercostal nerves, this nerve supply is secondary to the phrenic and is insufficient to carry on the action of the diaphragm after a division of the phrenic. 4. That a division of the phrenic nerve, producing a partial collapse of the lower lobe of the

lung on the affected side and an atrophy of one-half of the diaphragm, might predispose to infection of the lung or be followed by a diaphragmatic hernia. 5. That a division of one phrenic nerve in man, resulting in paralysis of one-half of the diaphragm only, is not necessarily fatal."

**63. Angina Pectoris.**—Robinson finds typical angina pectoris a rare disease, while the pseudo-angina is comparatively frequent. He thinks the latter is generally of neurotic character, but would be slow to admit the existence of true angina of purely neurotic origin. He reviews the symptoms and etiology at length and remarks in regard to the treatment. Of course, for the treatment of the attack the vaso-dilators—the nitrites and nitroglycerin—are the standbys. The condition of the heart is to be looked after, the hygiene of the patients attended to, and over-exertion, exposure to wind, great heat or cold or rapid changes carefully avoided. The article is too detailed to be fully abstracted.

**66. Herpes Zoster.**—In a former paper entitled: "Is Herpes Zoster a Cause of Pleurisy and Peritonitis?" Curtin raised certain questions which he thinks he can now better answer. A number of cases of herpes are reported complicating pleurisy, Bright's disease, localized peritonitis, meningitis, etc., and rheumatic affections. Their study seems to indicate that inflammation of the serous membrane precedes a zoster, therefore inflammation causes the eruption. The cases here reported settle at least some of the problems suggested in this former paper.

**67. Malignant Tumors.**—Anzinger has investigated the changes occurring in striped muscle in the neighborhood of malignant tumors in a large number of cases, including 30 cases of cancer of the breast, infiltrating the pectoralis, 15 of epithelioma of the lip, and others of carcinoma and sarcoma involving different portions of the body and affecting the adjoining muscle tissue. The changes produced in muscle by invading carcinoma are more marked than those produced by sarcoma, but do not differ essentially in kind. Those produced by sarcoma are chiefly mechanical; those due to carcinoma are mechanical, nutritive and metabolic. Evidences of toxic action are more marked in the latter than in sarcoma. Carcinoma acts more as an active injurious foreign body upon muscle than does sarcoma.

**70. Nasal Osteophytes.**—MacCoy finds the presence of these bodies in the nasal chambers generally situated well back underneath the lower turbinated bone, on the bony septum, and on the floor of the nose, varying in size from a sharp spicula to the small irregular mass. The summary of his paper is as follows: "1. Under an anesthetic, with the little finger as an intelligent probe, certain osseous structures foreign to normal nasal conditions may be found. 2. These osseous masses are osteophytes, having the anatomical structures of such bodies. 3. Osteophytes, clinically, are new conditions to be considered and studied. 4. In operations for deflection of the nasal septum, lack of complete success may result from their presence. 5. Osteophytes are loose in structure and readily removed by proper instruments."

**78.** This article has appeared elsewhere. See THE JOURNAL of February 15, 1911, p. 477.

**79. Tropical Diseases.**—In this concluding instalment Andrews describes the symptoms of ankylostomum duodenale as described by him in the Philippines. He states that alcohol, oils, turpentine, etc., and glycerin are all solvents of thymol, and if these should be given while thymol is being administered, there is grave danger of poisoning; also, unless the patient is properly prepared by rest and feeding, it is dangerous. Nevertheless, it was the treatment generally used in the army. The patient was put on a liquid diet for two or three days and the bowels freely opened. On the next day no food was allowed, and then usually 20 grains of well triturated thymol was given in capsules every hour for three hours or until 60 grains had been taken. If the bowels did not open spontaneously, another aperient was given, usually a seidlitz powder, four or five hours after the last dose of thymol. One such course of treatment may be sufficient, but it is well after a week has elapsed to

again examine the feces and if ova are present to repeat the treatment as before, once or oftener. Male fern is given in the same dose as thymol, but was not used after the thymol treatment was introduced. Prevention of contamination of soil and water constitute the prophylaxis. There was frequent disease of the gums; some of these cases may have been sprue. Some of the patients had diarrhea and dysenteric symptoms besides the sore mouth. The various forms of dysentery are noticed in conclusion.

**87. Rectal Examination for Life Insurance.**—Mason calls attention to the rectal conditions which may affect the expectancy of life. He does not advocate thorough examination in all cases, but where anything indicates disease in this region it should be attended to.

**89. Skin Diseases and Longevity.**—Besides the specific skin disorders, cancer and leprosy, there are a number of other cutaneous troubles which have more or less to do with underlying conditions that may affect the longevity of the sufferer, such as glycosuria and the serofulides, which, if not tuberculous, are probably luetic. The everyday affections which make up the work of the dermatologist, such as acne, eczema, psoriasis, erythema, parasitic disease, impetigo, lichen planus, etc., have not a very marked influence on life duration.

**111. Heart Diseases in Pregnancy and Labor.**—The recognition of the importance of the condition of the heart in relation to pregnancy and labor is largely a matter of the last 30 years, and the text-books before 1871, as a rule, made little mention of it. It is well known that many patients of this class pass through pregnancy and labor without difficulty. Nevertheless it is a matter of serious importance, in some cases requiring the physician's most careful attention. So far as we can judge from the statistics, the most fatal lesion is mitral stenosis. There is, of course, a certain amount of disturbance of the heart in normal pregnancy, but true valvular disease rarely begins in this condition and acute endocarditis is rarely found. When it does occur it must be regarded as more serious than in non-pregnancy. The effects of pregnancy on the woman who has valvular lesions vary greatly and depend upon a variety of factors, such as the extent of the disease, the degree of compensation existing, the general health, habits, etc. There is always a danger, especially when the disease is recent, that fresh fibrin-vegetations may form on the valves, owing to the increased hyperinosemia of the blood. The pregnant woman has, other things being equal, a short life expectancy if she exercises the function of child-bearing, and the danger is increased with succeeding pregnancy. When the compensation is perfect, she may pass through with no more trouble than in normal cases, but in mitral disease, especially where stenosis exists, the most marked symptoms occur. They usually supervene after mid-term, but may develop earlier. The majority of cases which go to term become worse during the last weeks. As regards the influence of cardiac disease in deciding the question of marriage, different views are held. It is very commonly taught that a woman with weakened heart should not marry if her well-being alone be taken into consideration. Some would insist on this restriction only in such cases as mitral stenosis, when the woman's health is not good or some other bodily lesion exists. Careful hygiene should be observed during pregnancy. Where no abnormal symptoms occur no medical treatment is required, but tonics where needed and heart tonics for strengthening the heart muscle. When digitalis is used, a nitrite should also be used to counteract the effect of digitalis in increasing the blood pressure. If the heart failure seems to show, most authorities claim the pregnancy should be terminated, especially when the more severe signs are present. This should be done in the majority of cases, but it should be remembered that the procedure may be as dangerous as a full-term labor, especially when cardiac symptoms are marked. The greatest danger is at the end of the third stage of labor, especially in mitral stenosis cases. The circulation in the uterus is practically checked, the organ being quite anemic and the circulation in the extra-uterine tissues greatly interfered with. This alteration in the circulation

throws an extra burden on the already overworked heart, and paralysis may follow. Fritsch's view that death occurs from syncope on account of an insufficient amount of blood reaching the heart, is not proven. When labor occurs the patient should be carefully watched and kept quiet through the first stage. She should not be allowed to pass through the second stage on her own strength, especially if mitral disease exists. Chloroform should be used. Webster advises nitrite of amyl given by inhalation. Hypodermic injections of nitroglycerin may be used. In the third stage, according to his theory of overworking of the heart, the indication is not to conserve but to allow the free escape of a certain amount of blood from the body in order to prevent over-distension of the lungs and the right side of the heart. The patient is kept under chloroform, ether is given hypodermically from time to time, and the nitrite tends to counteract the contractibility of the uterus, and so delay the separation and expulsion of the placenta. This should not be allowed to take place naturally and neither the Dublin or Credé method should be used. The best method is manual separation; allow a certain amount of blood to escape through the torn sinuses, but watch it carefully and watch the heart also at the same time. He thinks that it is not necessary to bleed the patient from other parts while the easy method of bleeding from the uterus is possible. The treatment of these cases during the puerperium is of the greatest importance; rest in bed for several weeks, stimulants, administration of heart tonics, easily digested nourishing food, no straining, the bowels regulated so as to move easily and catheterization for some days, complete quiet and good nursing are imperative. The patient should lose no sleep or be disturbed, and as soon as the stomach is able to bear iron it should be given.

**112. Butyric Acid.**—Salisbury has tried a new test for butyric acid in the stomach which was published by Knapp, of New York, in the *Medical Record*, Nov. 10, 1901, and finds that it is not sufficiently delicate for clinical use. Butyric acid, unless present in large quantities, does not interfere with titration of free HCl. by the use of dimethyl-amido-azo-benzene as an indicator. Butyric acid may be readily separated from the stomach contents by distillation in a side-neck test-tube, and may be recognized by its odor when contained in moderate quantities.

**121.**—This article has appeared elsewhere. See *THE JOURNAL* of February 1, [12, p. 351.

**122. Mastitis in Typhoid.**—This is apparently one of the rarest complications of typhoid, occurring much less frequently than orchitis, thyroiditis, or parotitis. McCrae, however, reports two cases and sums up his conclusions as follows: "1. Mastitis is a rare complication of typhoid fever, and usually occurs late in the attack. 2. It occurs in both sexes, and is apparently not associated with a functioning gland. 3. Both breasts are involved in about one-half of the cases. 4. Suppuration occurs in about half of the cases, and may be associated with the typhoid bacillus or staphylococcus. 5. It is of no special moment in the prognosis."

**130. Movable Kidney.**—Cartledge finds the right kidney much more susceptible to displacement than the left, and he thinks that 15 per cent. of all women who consult physicians for pelvic or abdominal disorders are thus affected. He thinks that tight lacing, chronic constipation and pregnancy, together with the great frequency of gall-bladder disease in women, are sufficient to account for the greater frequency in that sex. He also holds that movable kidney of the right side is frequently associated with chronic changes in the appendix. Whether this is entirely one of effect or should be considered a contributory cause he is unable to say. He has removed the appendix in every case of movable kidney operated on by his method of removing by one incision, which he describes. That there is a connection between movable kidney and chronic appendicitis he is inclined to believe. The restless kidney probably does adjacent structures more injury than it sustains itself. The descending colon and cecum are kept in a chronic state of congestion or irritation. In conclusion he describes his method of operating. The incision should begin an inch external to McBurney's point and be directed upward, outward

and backward for five inches. The tip of the twelfth rib is the objective point above. Separate aponeurosis and muscle fibers of the external oblique, split internal oblique with scissor point and thoroughly retract by retractors; open the peritoneum in the usual way through a small incision, and explore. Draw cecum, if not fixed, into the wound and close the peritoneum with running gut suture. Split the fibers of the transversalis and grasp in the same retractor as the internal oblique. At this stage of the operation dilatation by traction is the secret to easy access. Render the muscle patulous to succeed. In splitting the fibers of the internal oblique the rather large size of the last dorsal nerve will be observed. Next split the peritoneum from the transversalis fascia, beginning at the lower end of the incision. This is best done with a flat sponge. The split in this transversalis runs as far back as the thick aponeurosis known as the lumbar fascia. Place a wide retractor against the colon, draw it toward the median line, enter under the lower costal arch lifting the same. These retractors will keep muscles separated as well. We are now in a position to work with the greatest ease and accuracy with the patient in the dorsal position, though slightly inclined to the opposite side is best. With this control of the operating field, Cartledge believes it possible to suture the kidney so that it will remain stationary.

**131. Modern Small-Bore Projectiles.**—Butler's article describes the effects of bullets from the American army rifles, illustrated by cases showing the effects at short range in the soft tissues, which may be extreme even in the muscles. He has not found as much tendency to split up as with the old projectiles, little infection of the wound and lodgment rather exceptional at long range. Primary hemorrhage is more apt to occur than with the old weapons. In the explosive zone hard bone is often shattered in many pieces with the fragments scattered over large areas, but the bone area decreases as the range increases. There are many cases on record where perforation has occurred at medium and long range with apparently little damage and where the damage from perforating wound of the hard bone is often slight. Chest wounds are less dangerous with modern projectiles, but wounds of the abdominal viscera, especially the glandular organs, show an explosive effect often up to 1000 yards or more. Wounds of the cranium are often disastrous even at long range; at the extreme range of 2000 to 4000 yards, a hit is exceptional. He has not been able to get much data of such cases, but he is inclined to think that the wounds are sometimes very severe, owing to the so-called "tumbling" effect of the bullet.

**143. Drainage in Appendicitis.**—Westbrook takes up the subject of drainage and summarizes his conclusions as follows: "1. There are as yet no well recognized formulæ to guide the surgeon as to when to omit drainage in purulent collections attending appendicitis. 2. While it is true that the peritoneum may be relied upon to take care of a certain quantity of infectious material, we have no means of estimating in any individual case what that quantity may be. It is contrary to experience to expect the peritoneum to care for any large quantity of infection, otherwise we would never have to operate at all for appendicitis, or septic peritonitis. 3. An estimate of the individual's resistive powers to infection may be approximately made by the usual methods of consideration of the conditions of his lungs, kidneys, etc., his pulse and temperature, his previous health and talents, and perhaps, in some instances, by the amount of leucocytosis found on blood examination. But we have no means of placing over against this, at the time of operation, an accurate estimate of the amount and virulence of the infection with which the patient's resistive powers will have to contend. We can not estimate any individual susceptibility or immunity to infection which he may possess. 4. If the surgeon decides to omit drainage in any case of appendicitis with outlying infection, he must do so relying entirely on his personal ability to estimate the clinical facts in the case, and the nature and extent of the pathological process exposed at operation. Then, if his previous experience has brought him to the point of omitting drainage, he is warranted in doing so. 5. The majority of surgeons the world over still consider drainage necessary in all degrees of the

class of cases under discussion, and that we must consider the safer teaching."

147.—See abstract in *THE JOURNAL*, xxxvii, p. 48.

**153. Pelvic Lesions in Insanity.**—This latest of Hobbs' papers on the subject gives the results of numerous operations in various forms of insanity with special reference to the effect on the mental disease. The operations included ovariectomy, replacement of the displaced uterus, cervical diseases, diseases of the uterine body and of the perineal body. His figures are certainly favorable to the results of operation, but most of the cases where recovery occurred were of the acute type and the exact relation of the operation to the recovery is not so evident. The most significant cases were the chronic mania and melancholia recoveries and the elements of time and recurrence are here to be considered. The paper is not so detailed in regard to this point as might be desired.

161.—This article has appeared elsewhere. See *THE JOURNAL* of January 25, [147, p. 281.

**166. Protargol.**—The use of protargol in eye disorders is advocated by Hiers, who reports cases and offers the following deductions from his experience: "1. On account of its non-coagulability of albumin and albuminous products, and the facility with which it can be indiscriminately combined with the alkalies and local ocular anodynes, protargol possesses a marked advantage over silver nitrate. 2. As contrasted with the latter in the therapy and prophylaxis of gonorrheal ophthalmia, protargol does not undergo chemical changes nor decomposition; and is advantageous in that its action is non-caustic and unirritating. 3. The harmlessness of protargol renders its application easy and safe. 4. Protargol, while exercising remarkable penetrative power, will not stain the mucous membrane nor sear the tissues. 5. Its penetrability enables it the better to undermine and eradicate diseased conditions; which faculty, in a measure, is denied nitrate of silver, on account of the pseudo-membrane eventuating from its application. 6. For general prophylaxis simple washing of the eyes with protargol is sufficient; but where gonorrheal infection has been proven, or is suspected, instillation is indicated. 7. As a routine measure, washing the eyes with protargol should be made obligatory in private obstetrical practice. 8. Protargol should be advocated and substituted for silver nitrate in clinics. It possesses all of the advantages with none of the disadvantages of its silver salt. 9. Protargol is reliable, safe, certain and quick in the therapeutics of ophthalmia neonatorum and trachoma if used in sufficient strength and with proper frequency. 10. In my practice and experience it has manifested itself the remedy par excellence in those conditions in which its employment has been indicated."

3. Surgery of the Kidney.—The importance of the knowledge of anatomy of the kidney itself is first mentioned by Kelly, who confines his article to the methods of incising, searching and suturing of that organ in case of calculous extraction. The presence or absence of stone can be determined with tolerable accuracy by the x-ray, which has simplified modern surgery. He finds the ureteral catheter of value in two ways. In the first place, before the operation the catheter is passed up the ureter into the pelvis of the kidney, which is then thoroughly irrigated and washed out by letting water flow into it from the funnel, in this way distending the pelvis. The water then escapes into the bladder, and out into a receptacle through a urethral catheter. Boracic acid or a weak carbolic solution can be run through the kidney, in this way washing away the pus and rendering the surfaces relatively clean.

The second use of the catheter is, after washing out the pelvis, to leave it *in situ*, and then to expose the kidney by lumbar incision. Before incising the kidney, however, fluid is forced rapidly into the renal pelvis, so as to distend the pelvis and cause the kidney to swell up, making prominent certain surface landmarks as guides for correct incision. If the kidney is grasped in the full hand during the distension the exact position of the calices can be detected, as it alternately swells and collapses as the fluid is forced in. Any sacculation or local thinness of the cortex is also made evident, and the incision is best made there. In normal kidneys this distension is almost imperceptible on the convex surface, but with calculi present the antero-posterior diameter is sometimes increased 1.5 c.c. Lobules of the kidney are made prominent and the fibrous vascular septa between them are readily distinguished when the kidney is distended; there is less injury to the cortex from incision in this distended condition and the gush of water at once serves to show the entry into the pelvis. Sometimes a small stone is washed out in this way, saving further trouble. The irrigation of the pelvis through the incision by means of the renal catheter can be kept up as long as the catheter is kept in and the wound remains open. The most important point in the surgical treatment of renal calculus is the locality for the incision. Broedel's researches have shown that the vascularization of most kidneys is provided for by two arterial systems which are completely separated by the renal pelvis. There is a major system carrying three-fourths of the arterial blood providing for the anterior and part of the posterior half of the kidney, and a minor system carrying one-fourth of the arterial blood providing for the remaining posterior portion. These facts are illustrated by drawings in the article. The nearer the surgeon makes his incision in the line which divides these completely separated systems, the less blood is lost, whereas if he strikes the major vessels the hemorrhage may be frightful. The greater the distension of pelvis and calices the wider the separation of these systems; while in the normal undistended pelvis there is rarely more space than a few millimeters between the anterior and posterior vascular planes; in distended pelvis these are not infrequently parted by as much as 2 cm. or even more. If the kidney is examined attentively it will always be found to be divided up into irregular areas (the bases of the pyramids) the size of the end of a thumb. These areas are bounded by lighter colored lines which are often slightly depressed. These whitish lines represent the columns of Bertini, which extend up between the pyramids forming the framework which supports and carries the vessels. The white lines come together in a longitudinal white line on the anterior surface, which he proposes to call Broedel's white line. When the white line dividing the pyramids can not be found readily, their position is often marked by little groups of stellate vessels. The best place then to incise the kidney is down through the lateral portion of the posterior pyramids between the anterior and posterior vascular trees. The worst possible incision is the one which follows the course or wounds largely the vascular column found in cortical septa between the pyramids. In order, then, to make a correct incision one must cut parallel to Broedel's line and parallel to the posterior surface of the kidney, leaving about three-fifths of the kidney anterior and two-fifths posterior to the incision. The cut must be extended in a parallel direction to the posterior surface and not angling toward the center of the kidney as one would naturally incline to do. Through such an incision both anterior and posterior systems of calices can be readily explored. In about two-thirds of the kidneys these landmarks will prove reliable, but there may be an abnormal arrangement, slipping the least vascular plane forward so that it comes to lie in the plane of the median section or may extend even into the anterior portion of the kidney. Conditions of this kind, as a rule, are recognized: 1. By the form of the kidney, which shows Broedel's longitudinal white line not on the anterior surface but further back, as well as by the bulging of the posterior surface of the kidney, which is much flattened in normal cases. 2. By the arrangement of the large arterial trunks at the hilum. If the palpating finger feels as many vessels entering the parenchyma anterior to the pelvis as posteriorly, this

would be an indication for an incision through the middle of the lateral convex border. If there are even more vessels posteriorly to the pelvis than anteriorly, which is extremely rare, the least vascular plane would be found in the anterior third of the kidney. To reiterate, the incision should pass parallel to the longitudinal white line, 1 cm. away from it and on the same side of the kidney where the palpating finger feels the lesser number of vessels, in the majority of cases on the posterior surface, but occasionally anteriorly. Where the renal pelvis is not divided, after extracting the stone, the remaining calices are explored with a steel curved handle attached to a blunt knife which would at once reveal the presence of even a small stone by the grating sensation conveyed. If a stone is found the blunt curved handle may be pushed up into the calyx and the incision made down through the prominent part of the corresponding pyramid, and the stone extracted in this way through a small additional incision if it can not be lifted out with forceps through the original incision. Kelly has often, in fact, resorted to two incisions in the upper and lower poles separately, so as to spare the median portion of the kidney. It is best, as a rule, not to try to remove the stone primarily from the pelvis of the kidney without incising the renal tissue proper. He would resort to this only where the stone is known to be a small one, and there is no inflammation or edema of the pelvis, and where the pelvis can be incised, exposed and sutured without much difficulty. In closing the kidney wound we have three sets of sutures which may be used to advantage. One of fine catgut placed between the calices including the fat and fibrous tissues without involving the mucous surfaces, thus approximating the pelvis. The second series and the most valuable as devised by Dr. Hunner and Mr. Broedel are one or two series of mattress sutures, introduced with a straight, slightly-blunted needle, extending through the entire substance of the kidney. These give a perfect and sufficient control over bleeding. Finally, for perfect accuracy the capsule may be closed by a continuous catgut suture.

4. "Stammering" of the Bladder.—The symptom sometimes complained of by young males that urination is sometimes impossible in the presence of anyone is accounted for by Fenwick by the tonic spasm of the compressor urethræ, and the cure of the trouble is a section of that muscle. He gives his reasons for believing this the cause, which seem conclusive, and that the muscles around the neck of the bladder are not responsible. In some cases a stricture induces a spasm, and division of the stricture cures it. Fenwick says it is perhaps true that the relief often afforded by perineal section in deep-lying strictures with spasm is due not so much to drainage of the bladder as to division of the compressor urethræ. He would go further and say that some of the misery of tubercular ulceration of the bladder is induced by reflex spasm, and much of the relief supposed to result from temporary perineal drainage for this disease is due to division of the compressor urethræ. In some cases of vesical irritability in women which are relieved by exploration of the bladder with the finger, the beneficial result is due to overstretching the sphincter muscle, the analogue of the male compressor urethræ. In cases of prostatitis, where there is delay before micturition and a sense of obstruction, these are due to inflammatory swellings in the neighborhood of the urethral orifice of the bladder, and are in no way connected with true stammering, or benefited by section of the compressor. The same holds true in senile prostatic enlargement.

7. The Heart of the Child.—The importance of the study of the heart of the child is dwelt upon by Lees, who says it can be examined by the same methods as employed for the adult. He gives directions how to go about this without alarming the patient. Percussion will not be troublesome or objected to if done lightly with the fingers only. What the child allows is exactly what the physician ought to use. First, however, warm your hand and lay it gently over the precordial region to feel the cardiac impulse, its strength and whether it is localized or diffused. It gives information as to the strength of the left ventricle. Then shift the hand to the epigastrium and notice whether any impulse of the right ven-

tricle is to be felt there. If so, there is some congenital malformation or some disease of the lungs or left heart. Then pass the hand over the hepatic region and see whether it meets the resistance of an enlarged liver, and try very gently to feel its edge. Passing then to percussion, what we really want to know is the exact size of the heart. We can determine very little by physical examination as regards the size of the left auricle and only an approximate opinion can be formed as to the size of the right ventricle, but that of the left ventricle and of the right auricle can usually be determined with considerable accuracy. Use a terminal phalanx of the finger of the left hand for the pleximeter, pressing it gently but firmly on the spot and let no other part of the hand touch the chest wall, thus avoiding conduction of resonance from elsewhere. First select a spot in the mid-axilla and percuss here with the lightest possible stroke, then gradually shift your percussed finger towards the sternum and you will readily notice a change of note when the border of the heart is reached. Though the left lung apparently overlaps the heart it is thin and airless, and does not require deep or heavy percussion to recognize it. Expect to find the cardiac margin a little to the left of the position of the impulse. The left border of the cardiac dulness in health extends a little to the left of the position of the impulse and when dilated this may amount to a finger-breadth or more. Next determine whether the dulness extends to the left of the nipple itself and if so to what amount in the nipple acromial line. Two points on the border of the left ventricle thus determined, the line connecting these should correspond to this border. Next determine the size of the right auricle. Dulness due to it may always be detected in the fourth right intercostal space. In the third intercostal space the resonance should extend to the sternum and in the fifth space the hepatic dulness alters the note, but in the fourth space the right auricle dulness is present for about one finger-breadth in an adult and rather less in a child. In dilatation it may extend to two or three finger-breadths. When the dilatation is very great it may amount to three finger-breadths in the fourth space, one and a half in the third, and may even be detected in the second. The correct determination of the size of the right auricle is a matter of the greatest importance and indicates the necessity for leeches to relieve this condition, but nothing is so universally neglected. By this time you are ready for auscultation and the child is more ready for you and is not alarmed by the production of an instrument. In auscultating the heart of a child, be on the look-out for murmurs due to congenital malformation. Some of these are very peculiar and puzzling. The most frequent is a systolic murmur, loudest at or just below the junction of the left fourth costal cartilage with the sternum, probably often due to an incomplete cardiac septum. The next most common perhaps is a systolic murmur over the pulmonary artery, indicating obstruction there. Congenital murmurs are systolic in time; a presystolic or diastolic congenital murmur is exceedingly rare. Congenital malformations of the heart mainly affect its right side, which is most active during intra-uterine life. After birth this is less liable to disease than the left, though the tricuspid valve does not always entirely escape in rheumatism. But the most important affection of the right heart is secondary to active or extensive chronic disease of the lungs or to disease of the left heart, and careful watch must be kept on the amount of distension of the right auricle. The author speaks particularly of the importance of this and attention to it every day, especially in cases of pneumonia, and the need of local blood extraction with leeches for relief. Pallor of the face and smallness of the pulse are not necessarily contra-indications. These symptoms will improve after the right side has been relieved. In acute bronchitis, chronic bronchitis with an acute exacerbation, in whooping cough with its mixture of collapse, broncho-pneumonia, and emphysema, and in asthmatic attacks we should always notice the amount of distension of the right auricle, also in all cases of disease of the left heart especially after rheumatism. If dilatation of the right auricle is rapid, dyspnea and cardiac depression will probably be present, but the more gradual increase will only be revealed by percussion. As time passes the heart ac-

commodates itself and comparative comfort may be attained while heart dilatation still exists, but the condition is one of unstable equilibrium and another rheumatic attack may turn the scale. With this trouble the liver enlarges and if you find it down to the umbilicus or lower and the amount of urine passed be decreasing there is no time to be lost. Prompt venesection or leeching may be resorted to and the hypodermic use of strychnin to restore compensation. He calls attention before leaving the right side of the heart to a systolic murmur over the tricuspid region which is not very uncommon in healthy children and does not indicate any organic disease. On the left side of the heart the auricle is inaccessible, but the enlargement of the left ventricle, which is probably shared to some extent by the right, can be easily determined by careful percussion, and the strength of the ventricular muscle can be fairly estimated. It is very important in children out of health to get a clear idea of the left border of the cardiac dulness. In normal children this left border is usually distinctly internal to the nipple line. It may sometimes reach to but rarely goes beyond it. If we find the left limit one-half to one finger-breadth external to the nipple line, as is frequently the case, the matter is not unimportant. The cardiac muscle of the child is specially susceptible to poisons and the most characteristic instance of this is in diphtheria, which is much more fatal in children owing to the disease of the heart muscle. If the dilatation after diphtheria amounts to two finger-breadths to the left of the nipple line the case should be very carefully watched, as the danger is great. If it is only one finger-breadth we must bear in mind that it may suddenly increase. Enlargement of the ventricle always occurs in influenza, but the danger here seems less in children than in adults. In rheumatism the toxic effect on the heart does not seem to be so great. In typhoid, tuberculosis, debility and anemia as well as in renal disease, dilatation of the left ventricle is common and may be due to toxemia. The same is true in chorea, where with rheumatism it does not seem to be entirely the result of toxemia; but in rheumatism we are dealing with inflammation of the child's most important organ, probably caused by the local presence of a pernicious micro-organism. As for remedies he remarks that sodium salicylate in adequate doses seems to be distinctly antagonistic to rheumatic processes. The child bears salicylate well, and it rarely causes any troublesome symptoms. Sodium bicarbonate may be given along with it to advantage. Leeches are useful in repressing cardiac inflammation and local ice-bag applications. Ice is undoubtedly depressing to the normal heart, but when preceded by leeches and used with care it is the reverse to the rheumatic heart. Digitalis is of little service in rheumatic cardiac inflammation. Its value comes later when the inflammation has subsided and the mechanical effects manifest themselves. In ventricular dilatation and enfeeblement caused by toxemia leeches and ice are inapplicable. The hypodermic injection of strychnia is here mentioned as of value. Iron is of some use, but in diphtheria Lees relies mainly on the subcutaneous injection of atropin when danger threatens.

**8. Blackwater Fever.**—O'Sullivan-Beare gives his observations on the native treatment of blackwater fever with a decoction made from the root of a plant which he finds in East Africa and which has been described by E. L. Holmes as a new species, the *Cassia beareana*. He has had a fluid extract made of it with which he has had the best effects, but the native method of using it is also effective; it seems to be non-toxic and harmless in large doses. The fluid extract he has given in doses of one fluid dram well diluted in water every two hours at first and afterwards at longer intervals. The natives use a decoction made from the root boiled in water for one-half hour and give it freely whenever the patient feels like drinking, either hot or cold. It seems from his results to be a valuable remedy in this condition.

11.—This article has appeared elsewhere. See THE JOURNAL of January 8, ¶9 and ¶10, p. 202.

**15. Ovarian Opothrapy.**—Dalché observed a polyuria, or at least a marked increase in the amount of urine, in patients taking ovarian extract. There was also an absolute and relative increase in the total of phosphoric acid, and the propor-

tion of urea was increased in 50 per cent. of the cases. The normal proportions of uric and phosphoric acid were re-established in two out of the six cases whose metabolism was studied in detail. He has had extensive experience with ovarian medication, and has found it effective in forestalling or curing many derangements of function. He also noticed that chronic arthritis deformans frequently followed dysmenorrhea, amenorrhea, metrorrhagia or pregnancy, as well as the menopause. This "asthenic gout of elderly women," as it has been called, suggests the possibility that it may be due to dystrophy of the ovaries and lack of function. He consequently administered ovarian extract in such cases. The deformed joints did not diminish in size under this treatment, but they did not increase, and the patients unanimously announced that the pains had decreased. The nearer the menopause and the more recent the onset of the arthritis, the greater the relief from the pain. An interesting fact noted was the marked improvement in the case of a young man under this treatment. This suggests that possibly the ovary and the testicle may contain a similar alkaloid.

**16. Pneumonic Meningitis.**—Savary says that he has never observed a case recover from pneumonic meningitis. A sudden rise in temperature after defervescence may be the only symptom to betray the meningitis at first. There are no special characteristics to differentiate the pneumococcus meningitis from others. It remains latent in about half the cases of pneumonia or at least is masked by the symptoms of the latter. Headache, delirium and immobility of the back of the neck are the principal symptoms, or the affection may run rapidly through the entire syndrome of a tubercular meningitis. Netter observed only 4 recoveries in 65 cases of the affection; death occurred between the first and the fourth day. Recovery is apt to be protracted. Hensinger witnessed a case in which it was not complete until after five weeks. Others have witnessed permanent nervous troubles left as the relics of the meningitis—epileptiform seizures, paralysis or contractures. Recovery is more liable to occur when the meningitis precedes the pneumonia. The development of the latter is frequently accompanied by the subsidence of the former. Treatment can be only symptomatic, cold local applications, leeches behind the ears, laxative water every two hours, blisters in the neck region and in case of great depression, camphor per rectum, one part to 60 parts of some emulsion.

**17. Efficacy of Apomorphin in Hysteria and Epilepsy.**—Faucher recommends one-tenth to one-fifteenth of a grain of apomorphin as a speedy means of arresting an attack of hysteria or hystero-epilepsy and even an epileptic seizure. The patient's attention is diverted by the injection, then follows the vomiting and the subsequent depression, the whole soothing and relaxing the nervous system and controlling the seizure. It is an actual specific against hysteria, he observes, whatever form it may assume. He describes a number of cases of supposed apoplexy, etc., promptly cured in a few minutes after the injection. The epileptic is usually inclined to eat too much, and the seizure frequently follows an abundant meal. The indications, therefore, are to relieve the digestive system and reduce the congestion of the nerve centers, both of which are promptly accomplished by apomorphin. The seizure is arrested and is not followed by others. Of course, apomorphin is by no means a specific against epilepsy, but it is a valuable means of controlling the attacks of certain neuroses in whose presence the physician is too ready to consider himself powerless.

**19. Treatment of Tuberculosis with Cinnamic Acid.**—Heusser of Davos Platz has previously published 22 cases of tuberculosis treated with cinnamic acid or hetol, and now adds 60 more to the list. The results have convinced him that this method of treating tuberculosis, within the limits established by Landerer, is entirely harmless and is more effective in inducing cicatrization and healing in cases of complicated tuberculosis than any other remedy yet recommended for the purpose.

**26. Inoculation of Cancer in Animals.**—Mayet discusses the results of an extensive series of experiments on animals

inoculated with cancerous matter. The tests on dogs and rabbits were always negative, but neoplastic lesions were induced in a number of white rats, when they had been inoculated merely with the soluble products of the cancer.

**28. Exaggeration of Knee-Jerk in Asthma.**—Monceorge examined 141 patients with asthma and found the knee-jerk very much exaggerated in 18 of the 66 men and in 29 of the 75 women. The knee-jerk was exaggerated to a certain degree in 30 of the men and in 34 of the women. It was normal in only 18 of the men and 12 of the women.

**30. Clinical Application of Hemolytic Substances.**—Lau-nois announces as the result of much experimental and clinical research, that normal human blood-corpuscles may be destroyed by certain organic fluids derived from diseased subjects, such as the serum, ascitic fluid or pleural effusion. On the other hand, the corpuscles of the persons from whom the fluid was originally derived are peculiarly resistant. The fluids contain, therefore, an alexin, a "sensibilisatrice" for human corpuscles and an antihemolysin. The hemolytic substance is variously called alexin by Buchner, cytase by Metchnikoff and complement by Ehrlich. The substance existing in the organic fluid which favors the action of the alexin and renders it elective, is called the sensibilisatrice in France, or the hemolytic antibody, preventive substance, immune body or amboceptor by Ehrlich, philocyctase or fixateur by Metchnikoff, and desmon and copula by others. All these various terms merely represent the hemolytic substance and the other substance in the serum which favors its action and renders it elective. Still other substances in the organic fluids oppose the hemolytic action and hence are called antihemolysins.

**35. Amylolytic Ferment in Children.**—Nobécourt describes his researches which established the fact of the frequent presence of an active amylolytic ferment in the blood serum even immediately after birth. This ferment is unquestionably secreted by the organism of the child and is not derived from the mother. There is no appreciable difference between this ferment found in the serum of the breast-child and of the child fed with cow's or goat's milk.

**36. Peculiar Form of Osteo-Arthritis of Hip in Children.**—Nové-Jossierand has observed a number of cases of children between 5 and 15 who began to limp a little, with occasional pain in the hip-joint. Abduction was slightly restricted. These symptoms subside spontaneously or after a few days' rest. They might be explained by a sudden congestion occurring in the midst of unusually rapid growth, but this explanation does not suffice for the occasional cases in which the symptoms persist during several weeks or months. A tubercular affection can be excluded on account of the final complete disappearance of all symptoms without much treatment. In a case described in detail, radioscopy disclosed a strange condition, which, without destroying the bones, affected them locally with a transient alteration, manifested in the enlargement at the periphery, and permeability to the  $x$ -rays in the center. Restitution was complete after a few months, and the functions and shadows of the joint returned to normal except for a slight hyperostosis of the supra-cotyloid region. The head is also a trifle thicker than in the other hip. The slight coxa vara noticed has entirely disappeared and the neck has resumed its normal slope. Immobilization was applied at intervals during a few months, and recovery has been complete for more than a year.

**37. Pleuritic Effusions in Persons with Heart Disease.**—Barié states that he noticed pleurisy with effusion in 13 out of 126 cases of heart disease. Hydrothorax can be differentiated from pleural effusion by its bilateral development, usually accompanying other tardy complications of organic heart trouble. A true pleural effusion is usually unilateral and on the right side, and even although small in amount, is liable to cause marked dyspnea. The pleurisy is, as a rule, of an inflammatory nature, the result of irritation of the pleura from the subjacent hemorrhagic infarct. The cytologic formula is like that of pneumococcus pleurisy, polynucleated and epithelial

cells predominating. The presence of polynucleated cells may disclose some preceding unsuspected hemorrhagic infarct. The pleurisy may not be directly dependent on the heart disease. It may be induced by some intercurrent attack of acute articular rheumatism. In a case of this kind in his service, the patient recovered under sodium salicylate in less than a month, and the rheumatism and pleurisy disappeared together. This rheumatic pleurisy is characterized by its sudden onset, by the extent of the painful area and by a tendency to invade the pleura on the other side in turn. In other cases, the same infectious or toxic influences which cause the heart disease, may induce pleurisy, as in case of malignant endocarditis. The pleuritic manifestations are merely the effects on the pleura of the same poison which causes the endocarditis. Hydrothorax is a very serious complication of heart disease, but the prognosis of pleurisy under the same conditions is more favorable, under appropriate treatment, simple and purely medical, purgatives, diuretics and revulsion. If the dyspnea persist and transient hyposystolic accidents develop, thoracentesis may be necessary even with a small amount of fluid in the pleural cavity. Hydrothorax requires general treatment of the underlying asthymy.

**38. Glycolysis.**—Lépine states that recent researches have fully confirmed his previous announcements that the tissue of the pancreas is endowed with the property of destroying substances which otherwise prevent glycolysis in the tissues. This property is distinct from the internal secretion of the pancreas. He has succeeded in extracting a crystallizable substance from the urine of diabetic and other patients, which prevents glycolysis. This substance becomes destroyed in its passage through the vessels of the living pancreas in dogs and guinea-pigs.

**40. Hemoglobinuria After Quinin.**—Otto reports a case of quartan fever acquired in Poland, which was treated, after it had lasted four weeks, by a single dose of 50 cg. of quinin after the patient had returned to Hamburg. This was followed immediately by a typical attack of blackwater fever with hemoglobinuria. This is the first case on record, he remarks, which demonstrates that tropical conditions are not indispensable to the development of blackwater fever, and also that hemoglobinuria is liable to occur in the course of a quartan malaria. There was no idiosyncrasy to quinin as the patient had previously taken it without disturbance.

**41. The Plague.**—This article is issued from the Institute for Infectious Diseases in Berlin, and is thus an official contribution to the further study of the plague. It proclaims that the recent advances in our knowledge of the means of dissemination of the plague by rats renders a new international conference necessary, as the rulings of the conference of 1897 are now obsolete in many respects. The quarantine regulations adopted by the conference need revision, and the introduction of international measures against rats on ships and in harbor towns. Rats are to the spread of the plague what water is to cholera, and the successful results of prophylactic measures when the rats have been consciously or unconsciously destroyed or driven away, are the most important acquisitions to our campaign against the plague. In Egypt the rats were not directly attacked as the attempt was considered absolutely hopeless, but the disinfection of the houses, the destruction of accumulated garbage, etc., and the saturation of the houses with sublimate, had the unexpected effect of driving the rats away and keeping them away from human habitations, and it was thus possible to control and stamp out the plague. The principal prophylactic measure, however, is to destroy all the rats on a ship leaving an infected port. A single infected rat escaping to shore is infinitely more dangerous to the community than plague patients, as contagion from the latter can almost certainly be controlled. Ships can be cleared of rats by poisonous gases without injury to the cargo. The ship *Pergamon* recently arrived at Hamburg from an infected port with dead rats but no cases of plague on board. Prompt extermination of the rats before unloading prevented any infection of the crew or workmen unloading the ship. The Danyasz bacillus is uncertain in its results, but may be found useful in places where poisons can not be used, as in grain warehouses, etc. Protec-

tive vaccination or serum treatment is useful for persons directly exposed to the plague, physicians, nurses, etc., but can scarcely be applied on a large scale. In fact all the statistics collected to date in respect to their practical value, are unreliable or else compiled under such varying conditions as to exclude all comparative conclusions. Even in the recent tests at Cape Town the number inoculated, 10,000, was so small in proportion to the uninoculated, 120,000, that it is impossible to draw conclusive deductions from the results. Anti-plague serum promises well, and if suitable improved media and methods of cultivation for the plague bacillus can be discovered, which will produce in young cultures a soluble, powerful toxin, serum treatment may prove a valuable adjuvant in the war against the plague.

**43. Microscopic Examination of Human Milk.**—Friedmann has found that when nurslings are not thriving on breast milk, the microscope invariably shows a degenerated condition of the milk. Under normal conditions the fat globules are seen under the microscope to be of three sizes, small, large and medium. The medium and small ones are most numerous, and about 10 to 20 of the large are found in the microscopic field with a magnifying power of 400 or 500. If the proportion of large globules is more than this, the milk is harder to digest, but if the child can accomplish it, he thrives exceptionally on this milk. When the small-sized globules predominate, the milk is poor in quality and the child usually suffers from chronic dyspepsia, especially when the globules are very small and deformed or disintegrated. The globules usually crowd close together. This examination of the milk with the microscope is sufficient for all practical purposes and affords important indications for the physician. He should adopt it as a routine measure before recommending a wet nurse.

**44. Committee for Cancer Research.**—At the meeting November 14, it was decided to organize another collective inquiry among the surgeons of Germany to elicit new statistics in regard to the ultimate results of operations for mammary cancer. The main address was on the dissemination of cancer in Germany. It is to be published later in full. Hansemann is studying the cases of cancer discovered for the first time at the autopsy. He has already found that 131 or 18.42 per cent. of 711 cases of cancer had not been diagnosed during life. Von Leyden replied to the suggestion that the assumed increase in the number of cases of cancer is due to improved methods of diagnosis, that this can not be accepted as there has been little improvement in this respect in the last few decades. The question of the occurrence of cancer among the natives of Africa was discussed. The impression prevailed that it did occur but no definite statistics were offered.

**45. One Hundred Cases of Spinal Tropa-Cocainization.**—Schwarz does not include the cases in which he gave more or less than the dose of tropa-cocain which he finally decided was the most suitable. At this dose he never failed to induce analgesia reaching to the umbilicus and was thus able to perform every operation required below this zone, without pain or any disturbing after-effects. In a very few cases, after-effects were evident, but so brief and so mild that there is no comparison between them and those liable to follow the use of cocain. He concludes by proclaiming that he prefers spinal tropa-cocainization for appropriate cases to any kind of inhalation narcosis. He follows Tuffier's technique, and injects 5 cg. of tropa-cocain dissolved in 1 c.c. of water, then elevates the pelvis for ten minutes, after which he lowers the patient to the horizontal plane. He uses 6 cg. if the operation is to be on the hip-joint, but never more than 4 cg. if the patient is under 17 years of age. The analgesia in a few rare cases extended to the head. It always lasted one or two hours for the legs, genitalia, perineum and anus, but sometimes subsided in thirty minutes during operations for hernia, requiring a few whiffs of some narcotic to complete the operation. He does not recommend spinal analgesia for laparotomies, as, although the analgesia of the skin is complete, the patients are disturbed by the pulling and stretching of the intestines. The analgesia induced by tropa-cocain is perfect, and the few rare after-effects noted are merely the rudiments of what is liable to follow cocainiza-

tion. When headache does occur it is so trifling that the patients do not mention it unless questioned. After-vomiting was observed in only two cases, during the operation in only two, and nausea in two. The temperature did not rise above 38.2 C. in any instance. The youngest subject was 12, the oldest 78. Deerepit subjects with senile gangrene bore this method of analgesia with remarkable tolerance.

**48. Thymus Gland and Rachitis.**—Mendel calls attention to the great similarity between the symptoms exhibited by dogs whose thymus glands have been removed, and those observed in rachitis in children. He also suggests that the hypertrophy of the spleen noticed in rachitis may be due to its vicariously substituting the insufficient thymus gland. Friedleben found in examining the thymus gland in the cadavers of 300 children, from infancy to puberty, that the gland was abnormally small or abnormally large and hard in every case in which rachitis was certain or probable. In the cases of pronounced rachitis the gland was much atrophied. Reasoning from these premises, Mettenheimer has applied the extract of the thymus gland to the treatment of rachitis, following the example of thyroid treatment of myxedema. The success was not so striking as in the latter, but this was probably due to inadequate dosage. Mendel has been treating more than 100 rachitic children with thymus during the last five years, each child receiving as many grams of fresh gland substance as he was months old, or 6 to 12 tabloids a day. Even after exceptionally large doses, no by-effects were evident in any case, demonstrating the absolute harmlessness of thymus treatment. The rachitic process was favorably influenced in many cases. The functional disturbances were most rapidly and effectively controlled; the hyperidrosis diminished in two or three weeks; the sleep became more tranquil, the general appearance brighter and livelier. The symptoms recurred when the treatment was suspended for any cause, and vanished again on its resumption. Spasm of the glottis occurred less and less frequently until it finally ceased entirely. In one case in which a thorough course of phosphorus had not produced the slightest benefit, the spasms ceased completely after a few days administration of thymus tabloids crumbled in a tablespoonful of milk, and further treatment for three months banished all the other rachitic symptoms. The enlarged spleen usually commenced to subside after two or three weeks and gradually returned completely to normal size, as did also the distended abdomen. In one case the treatment was suspended for a fortnight on account of a stomatitis, and the spleen began to enlarge again. The rachitic alterations in the bones gradually returned to normal, dentition was promoted, the fontanelles grew smaller, and everything indicates that the skeleton is resuming normal conditions. When the rachitic process is definitely arrested, he found that 6 to 12 tabloids, according to the age of the child, twice a week instead of every day as at first, were sufficient to promote retrogression, although months were required for the complete cure. This method of treatment of rachitis aims to cure the rachitic symptoms by substituting the gland extract for the defective internal secretion, and to improve the general health. This improvement brings about a gradual restitution of the gland to normal, and by this means the definite cure of the tendency to rachitis. For this reason, if the thymus gland is irremediably injured by tuberculosis or congenital syphilis, it is impossible to anticipate a cure from it.

**53. Influence of Fractures on Circulation and Respiration.**—Fibich states that the temperature almost invariably rose in dogs after a subcutaneous fracture of a bone, especially when there was friction between the ends. The pulse was also accelerated for a moment, followed by a brief period of abnormally slow pulse. The latter was not noticed in curarized dogs. The higher temperature is frequently preceded by a depression of the temperature. All these phenomena occur so rapidly and so soon after the trauma that they are evidently independent of re-absorption or infection, and must be due to nervous influences.

**55. Sham Operations in Case of Imaginary Affections.**—Schächter relates a number of interesting experiences in regard

to neurasthenic patients who clamored for an operation on account of some fancied deformity or lesion. The results were always unfortunate when their requests were complied with, as the morbid fancy was not cured and always recurred in the same or another form. Reassuring, harmless suggestion is alone applicable in such cases, and sham operations should always be avoided for numerous and cogent reasons, which he enumerates.

**60. Differentiating Study of Bacteria with Capsules.**—Claermont's researches on bacteria with capsules are summarized in tabulated form, including the results of the inoculation of mice, guinea-pigs and rabbits, the bio-chemical properties of the bacteria and the peculiarities of their cultures. He identifies the "ozena bacillus" with Friedländer's pneumonia bacillus, but distinguishes two varieties. One is found exclusively in the secretions of ozena and is not pathogenic for guinea-pigs. The other is seldom found in ozena secretions, but occurs frequently in the most diverse morbid processes and is pathogenic for guinea-pigs. The scleroma bacillus is another species. The bacillus lactis aerogenes should be differentiated from the pneumonia bacillus.

**62. Length of Life of Disease Germs in Droplets and Dust.**—Gaffky found that microbes retain their vitality much longer in dimly lighted than in sunny rooms. This may be one reason why disease germs flourish better in winter than in summer, owing to the lesser hours of sunlight. He points out that influenza epidemics have never occurred in Germany except when the weather has been long cloudy. The vitality is also directly proportional to the size of the particle of dust or moisture. The germ dies more rapidly the finer the particles. In his tests with droplets such as are expelled in speaking, sneezing or coughing, he found that the bacillus prodigiosus and the typhoid bacillus retained their vitality 24 hours in daylight; the diphtheria bacillus 24 to 48 hours in daylight and 5 days in a cellar; the tubercle bacillus 5 days in daylight and 22 days in a cellar; the fowl cholera bacillus 10 hours in daylight and 24 hours in the cellar; the staphylococcus pyogenes aureus 8 to 10 days in daylight and 35 days in the cellar; the streptococcus longus 10 days in daylight and 38 days in the cellar, and anthrax spores 10 weeks in daylight, and at least 3 months in the cellar.

**63. Natural Immunity and Bactericidal Sera.**—Wechsberg reviews the latest researches on this question and emphasizes the fact that serum therapy for man must be established on the principle that the "amboceptors" in the therapeutic serum must find their appropriate complements in the patient's serum. He agrees with Ehrlich that the non-success which as yet has attended the employment of typhoid and cholera serum may be due to the fact that the serum is derived from species of animals which are so distantly removed from man. The amboceptors of the animal serum can not find their special complements in human serum.

**66. Methylene Blue Test of Function of Kidneys.**—Assfalg has employed this test in 46 cases of various affections. He concludes from his experience that this test, with other clinical indications, may prove of some service to the surgeon, but the individual physiologic and pathologic conditions must also be taken into account. It is impossible to formulate an anatomic diagnosis from it any more than from the determination of the amount of hydrochloric acid in the stomach, but it aids in determining the functional capacity of the kidney. Even nervous disturbances in the organism are liable to influence the elimination of the blue.

**68. The Micrococcus Catarrhalis.**—Ghon presents evidence to prove that this microbe is pathogenic at times. It is able to set up a simple bronchitis without the co-operation of other microbes, or even a lobular or lobar pneumonia, with severe general symptoms. The infection it induces has no characteristic features. It resembles most closely that from the influenza bacillus and pneumococcus, and it is frequently associated with or precedes their invasion.

**69. Idiopathic Enlargement of the Esophagus.**—Strauss points out that analysis of the seventy cases of bag-shaped

enlargement of the esophagus which have been published, shows that it began to develop in childhood, at puberty or under 40. It is therefore probably the result of some constitutional anomaly. Gastropsis was noticed in 3 cases and probably was not sought in all. The stomach was vertical in some instances. The pressure of the aorta probably first starts the morbid process, inducing some slight erosion or ulceration of the wall of the esophagus. This in turn may induce spasmodic contraction of the cardia by reflex action, and by this means a depression is formed which in time develops into an actual diverticulum. He describes two cases in detail with the autopsy findings in one. In the other case the diverticulum had developed in childhood, and was referred to a trauma. The patient was able to force the food down into his stomach by drinking copiously of effervescing beer or pressing on the thorax when the lungs were inflated. The sound could not be introduced except when the esophagus was inflated at the same time. By introducing two sounds, one a flexible spiral sound with a thread fastened to the tip and passing through an eyelet in the side, thus enabling the lower portion of the sound to be drawn up into a curve at will, it was possible to locate the outlines of the diverticulum with the fluoroscope. The curved sound pushed the other sound around as it was rotated. He determined the size by adapting for the purpose a long, narrow rubber balloon such as Turek uses for his "pneumatic gymnastics" of the stomach. This was introduced empty and then inflated when in the diverticulum until the patient began to experience discomfort. By this means it was possible to estimate the size of the cavity much more accurately than by the usual method of filling and emptying it of fluid. It is applicable even when the cardia is quite permeable. He tested the permeability of the cardia by administering carmin by the mouth and watching for its appearance in the urine. Another aid in diagnosing the diverticulum was the difference in the noise when air was blown through a sound at different levels in the esophagus. In the attempt to distinguish between the contents of the stomach and of the diverticulum, the presence of ferment, sugar, and the degree of acidity are important points. Differentiation is difficult in case of gastric aepsia, but traces of some ferment will decide the question. Sugar speaks for the esophagus and against a gastric origin, but this test is unreliable after a meal of carbohydrates in case of motor insufficiency. The total acidity can only be accepted as testimony in case of gastric aepsia when there is motor insufficiency. In such a case he found the stomach acidity 40 to 95 while that in the diverticulum was 10 to 25.

**70. Myelitis Consecutive to Acute Disseminated Encephalomyelitis.**—Huismann proclaims that every myelitis is induced by bacteria and describes a personal case in which every feature indicated this origin. He remarks that other causes may create a predisposition, but they are unable to induce a myelitis without bacterial invasion. The predisposition to myelitis consists in a congenital or acquired alteration of the walls of the spinal vessels which favors thrombosis. Acute myelitis resembles embolism in its course, while the chronic form is more like primary arterial thrombosis. Acute myelitis either heals with sclerosis or becomes progressively chronic. In many cases the affection assumes the latter character from the start, but a predisposition is required in this case, while on the other hand, acute myelitis can develop without a preliminary disposition.

**71. Source and Solubility of Oxalic Acid Eliminated in Urine.**—Klemperer announces that the most favorable conditions for keeping the oxalates dissolved are afforded by the presence of at least 20 mg. of magnesia in 100 c.c. of urine and no more than 20 mg. of lime. The proportion of magnesia in the urine is not much modified by ingestion of salts of magnesia, but even this slight increase is sufficient to keep the oxalates dissolved. The food should contain little oxalic acid or lime and much magnesia. Spinach, cocoa and tea should be avoided, also foods containing lime, especially milk, eggs and fresh vegetables. The prolonged administration of 2 gm. of magnesium sulphate a day will aid in keeping the oxalates in the

urine constantly dissolved. The most favorable proportions are when the lime is to the magnesia as 1 to .8, 1 or 1.2, with 20 mg. of magnesia to 100 c.c. of urine.

**72. Treatment of Tuberculosis.**—Wyler believes in increasing the resistance of the organism in childhood by massage and gymnastic exercises to strengthen the chest, done by, or under the eye of, an expert. After losing two children in his own family from tubercular affections, he has strengthened in this way the other members of the family, who had each a phthisical habitus, and has witnessed the throwing off of this predisposition.

## Queries and Minor Notes.

### CONTAGIOUSNESS OF EARLY SMALLPOX.

WEST SUPERIOR, WIS., Feb. 12, 1902.

*To the Editor:*—The Health Department of this city has been subjected to criticism on account of keeping secret the occurrence of several cases of smallpox in one of our best hotels, by a morning paper, which concludes as follows: "Prominent citizens are complaining that the public are not being kept thoroughly familiar with the true smallpox situation in the city, so that the infected places can be avoided. They believe that the citizens can not act in conjunction with the health officials unless they have a correct understanding of the situation, and feel that the department has erred in keeping the situation secret." A statement of our Health Commissioner explains, in an evening paper, the situation, a copy of which I enclose: "The patient was taken sick four days ago and had the ordinary fever symptoms attending many such diseases; on the forenoon of the fourth day the characteristic symptoms of smallpox appeared and he was immediately removed. The disease is not contagious during that period. . . ."

It is something entirely new to me that smallpox should not be transferable from a patient, who is sick already for four days with so-called "ordinary fever symptoms." I beg the editor to inform me, kindly, if facts are known which corroborate this statement.

F. HERB, M.D.

*Ans.*—It is not safe to count on the non-contagion of smallpox at any stage of the disease from the initial fever to the very final disappearance of all relics. There are abundant facts to show that it may be contagious before a complete outbreak, though there is no doubt that the danger is greatest after the stage of pustulation and scabbing has begun. In a public institution recently a case was received and almost immediately diagnosed and removed before the eruption had fully broken out. Nevertheless in the course of time a number of cases developed without any other known cause. It is possible that an officer may, to avoid excessive alarm on the part of the public, say things to minimize the danger which he does not himself believe. Whether this is advisable or not, is questionable; but it certainly is not right to say that any case of smallpox in any stage is safe as regards communicability. Some authorities have even gone so far as to say that even in the incubation stage there is a possibility of conveying the disease, but there is not much evidence to show that there is danger before some symptoms of the disease begin to manifest themselves.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**INTERNATIONAL CLINICS.** A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia: with the Collaboration of Drs. John B. Murphy, Chicago; Alexander D. Blackader, Montreal; H. C. Wood, Philadelphia; T. M. Rotch, Boston; E. Landolt, Paris; Thomas G. Morton, Philadelphia; Charles H. Reed, Philadelphia; J. W. Ballantyne, Edinburgh, and John Harold, London, with Regular Correspondents in Montreal, London, Paris, Leipzig and Vienna. Volume IV, Eleventh Series, 1902. Cloth. Pp. 302. Price, \$2.00. Philadelphia: J. B. Lippincott Co. 1902.

**THE STANDARD MEDICAL DIRECTORY OF NORTH AMERICA,** consisting of Twelve Parts, including Directory of Physicians of North America, Medical Colleges, Medical Service of the United States, Medical Societies, Medical Practice Acts, Medical Publications (including Books and Periodicals), Mineral Springs, Drugs and Medicines, Medical and Surgical Products, Manufacturers and Life Insurance Companies. Handsomely Bound in Red Buckram, 824 Pages, Imperial Octavo. Price, \$10.00. Chicago: G. P. Engelhard & Co.

**ON THE ALTERATIONS PRODUCED IN THE LARGE INTESTINES OF DOGS BY THE AMEBA COLI, BY HEAT, AND BY VARIOUS CHEMIC**

SUBSTANCES, with Notes on the Anatomy and Histology of the Viscus. By H. F. Harris, M.D., Atlanta, Ga. A Research Carried on under the Auspices of the Nathan L. Hatfield Prize Committee of the College of Physicians of Philadelphia. Paper. Pp. 143. Philadelphia: Printed for the College. 1901.

A MANUAL OF OPHTHALMOSCOPY. For Students and General Practitioners. By J. E. Jennings, M.D. (University of Pennsylvania). Author of "Color-Vision and Color-Blindness," etc.; formerly Clinical Assistant, Royal London Ophthalmic Hospital, London. With 95 illustrations and 1 Colored Plate. Large 12mo. Price, \$1.25 net. Philadelphia: Published by P. Blakiston's Son & Co. 1902.

DIRECTIONS FOR CLASS WORK IN PRACTICAL PHYSIOLOGY. Elementary Physiology of Muscle and Nerve and of the Vascular and Nervous Systems. By E. A. Schaeffer, LL.D., F.R.S., Professor of Physiology in the University of Edinburgh. With Diagrams. Cloth. Pp. 76. Price, \$1.00. New York: Longmans, Green & Co. 1901.

MARKET MILK: A PLAN FOR ITS IMPROVEMENT. By R. A. Pearson, M.S., Assistant Chief of Dairy Division, U. S. Department of Agriculture, Bureau of Animal Industry. Paper. Pp. 193. Reprint from the Seventh Annual Report of the Bureau of Animal Industry. 1900.

OUTLINES OF ANATOMY. A Guide to the Methodic Study of the Human Body in the Dissecting Room. By Edmund W. Holmes, A.B., M.D., Demonstrator of Anatomy, University of Pennsylvania. Second Edition. Cloth. Pp. 185. Lancaster, Pa.: New Era Printing Co. 1902.

SIXTH ANNUAL REPORT OF THE BOARD OF MANAGERS OF THE SPRINGFIELD STATE HOSPITAL of the State of Maryland, Sykesville, Md., to His Excellency the Governor of Maryland. Oct. 1, 1901. Paper. Pp. 41. Baltimore: Sun Book and Job Printing Office. 1902.

CLINIQUE DES MALADIES DU SYSTEME NERVEUX, HOSPICE DE LA SALPETRIERE (1897-1898, 1898-1899). Cinquième and Quatrième Serie. Paper. Pp. 606 and 678, respectively. Price, 70 francs. Paris: Octave Doin. 1900 and 1901.

REPORT OF THE COMMISSIONER OF EDUCATION for the Year 1899-1900. Volume II. Cloth. Pp. 1368. Washington: Government Printing Office. 1901.

PRINCIPLES AND PRACTICE OF OPERATIVE DENTISTRY. By John Sayre Marshall, M.D. (Syr. Univ.), Dental Surgeon U. S. A. Cloth. Pp. 635. Price, \$5.00. Philadelphia and London: J. B. Lippincott Co. 1901.

MOSQUITO BRIGADES and How to Organize Them. By Ronald Ross, F.R.C.S., D.P.H., F.R.S., Walter Meyers Lecturer in Tropical Medicine. Cloth. Pp. 100. Price, \$1.05. New York: Longmans, Green & Co. 1902.

ANATOMY AND PHYSIOLOGY OF THE EYE, with Hints for the Preservation of the Eyesight. By J. Frederick Herbert, M.D. Second Edition. Cloth. Pp. 68. Price, \$1.00. Philadelphia: P. Blakiston's Son & Co.

HYGIENE FOR STUDENTS. By Edward F. Willoughby, M.D. Lond., Diploma in State Medicine of the London University. Cloth. Pp. 563. Price, \$1.25. London and New York: The Macmillan Co. 1901.

REPORTS OF THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN. Volume I. Session of 1900-1901. Cloth. Pp. 237. Price, \$5.00. Philadelphia: P. Blakiston's Son & Co.

THE PERVERTS. By William Lee Howard, M.D. Cloth. Pp. 388. Price, \$1.50. New York: G. W. Dillingham.

### New Patents.

Patents of interest to physicians, etc., Jan. 14, 21 and 28:  
691,143. Hernial truss. Richard Hummel, New York City.  
691,270. Water bandage. Charles H. Jones, Tempe, Ariz.  
691,290. Tank for medicating water. Charles W. Perkins, St. Louis, Mo.  
691,295. Exercising apparatus. Franklin Schneider, Cleveland, Ohio.  
691,224. Invalid bed-rest. John F. Wilkins, Norfolk, Va.  
35,580. Design, hot-water bag closure. Christian W. Meinecke, Jersey City, N. J.  
691,638. Vaginal syringe. Richard H. Eddy and J. B. Johnston, Providence, R. I.  
691,732. Device for therapeutic application of smoke. Philip J. Schreiber, Toledo, Ohio.  
691,681. Aseptic preparation from pancreas and producing same. Wilhelm Weber, Stolberg II, Germany.  
691,687. Capsule. Robert B. Wilson, Woodhaven, N. Y.  
692,043. Suspensory. Joel U. Adams, Cincinnati, Ohio.  
692,102. Nitrocellulose. David Bachrach, Baltimore, Md.  
692,139. Making hydrogen dioxide. P. L. Hulin, Clavaux, par Roupoux, France.  
692,061. Douche bench. Thomas F. McCullough, Memphis, Tenn.  
692,166. Medicine carrier. Jakob Schaffer, New York City.  
691,881. Registering faucet for syrup bottles. Francis E. Thompson and F. N. Young, Boston, Mass.

## The Public Service.

### Army Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the fourteen days ended Feb. 6, 1902:

Surgeon P. C. Kalloch, granted leave of absence for fourteen days from February 5.

Surgeon J. J. Kinyoun, department approval of June 28, 1901, granting leave of absence for four months, amended so that said leave shall be for one month and twenty-one days.

P. A. Surgeon A. R. Thomas, to proceed to London, England, for special temporary duty.

Asst.-Surgeon Taliaferro Clark, granted leave of absence on account of sickness, for fourteen days from January 16.

A. A. Surgeon J. T. Bullard, granted leave of absence for twenty-five days from February 1.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for two days.

A. A. Surgeon R. T. Walker, granted leave of absence for four days from February 18.

Hospital Steward E. S. Maguire, granted leave of absence for thirty days from February 5.

### Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending Feb. 8, 1902:

Asst.-Surgeon F. M. Furlong, ordered to Naval Hospital, Norfolk, Va., instead of to the *Topeka*, as previously ordered.

Asst.-Surgeon W. H. Ullsh detached from the *Annapolis*, and ordered to the Naval Hospital, Mare Island, for treatment.

Medical Inspector J. R. Waggener, detached from the *Constellation* and to duty at the Marine Recruiting Rendezvous, Boston, Mass.

Surgeon J. F. Urie, detached from the Marine Recruiting Rendezvous, Boston, Mass., and ordered to the Naval Dispensary, Washington, D. C.

Surgeon L. W. Spratling, ordered to duty at the Naval Hospital, Portsmouth, N. H.

P. A. Surgeon S. G. Evans, detached from duty at the Naval Hospital, Portsmouth, N. H., and ordered to the Pensacola Navy Yard.

Surgeon F. J. B. Cordeiro, detached from the Pensacola Navy Yard, and ordered to the *Constellation*.

Asst.-Surgeon C. M. Oman, ordered to the Naval Hospital, New York, for duty.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 7, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, Jan. 18-25, 5 cases; San Francisco, Jan. 19-26, 14 cases.

Illinois: Jan. 25-Feb. 1, Belleville, 1 case; Chicago, 5 cases; Danville, 1 case; Galesburg, 2 cases.

Indiana: Crawfordsville, Jan. 18-Feb. 1, 14 cases.

Iowa: Clinton, Jan. 26-Feb. 2, 6 cases.

Kentucky: Covington, Jan. 26-Feb. 2, 6 cases.

Louisiana: New Orleans, Jan. 25-Feb. 1, 4 cases, 1 death.

Massachusetts: Boston, Jan. 25-Feb. 1, 47 cases, 12 deaths;

Brookline, Jan. 18-25, 1 case; Cambridge, Jan. 25-Feb. 1, 5 cases;

Chicopee, Jan. 18-25, 1 case; Malden, Jan. 25-Feb. 1, 1 case; New Bedford, Jan. 25-Feb. 1, 5 cases; Somerville, Jan. 25-Feb. 1, 1 case; Waltham, Jan. 25-Feb. 1, 1 case; Woburn, Jan. 25-Feb. 1, 1 death.

Michigan: Ann Arbor, Jan. 11-18, 1 case; Detroit, Jan. 25-Feb. 1, 6 cases; Ludington, Jan. 26-Feb. 2, 1 case.

Minnesota: Minneapolis, Jan. 18-25, 23 cases.

Montana: Butte, Jan. 12-26, 9 cases.

Nebraska: Omaha, Jan. 25-Feb. 1, 51 cases; South Omaha, Jan. 24-31, 172 cases.

New Jersey: Camden, Jan. 25-Feb. 1, 7 cases; Jersey City, Jan. 25-Feb. 1, 25 cases, 1 death; Newark, Jan. 24-Feb. 2, 40 cases, 3 deaths.

New York: Jan. 25-Feb. 1, Binghamton, 3 cases; New York, 42 cases, 15 deaths.

Ohio: Cincinnati, Jan. 24-31, 16 cases, 1 death; Cleveland, Jan. 25-Feb. 1, 3 cases; Middletown, Jan. 25-Feb. 1, 2 cases; Toledo, Jan. 25-Feb. 1, 3 cases.

Pennsylvania: Auburn, Nov. 16-Jan. 25, 48 cases, 1 death;

McKeesport, Jan. 25-Feb. 1, 1 case; Norristown, Jan. 25-Feb. 1, 1 case; Philadelphia, Jan. 25-Feb. 1, 73 cases, 13 deaths; Pittsburg, Jan. 25-Feb. 1, 1 case; Williamsport, Jan. 25-Feb. 1, 2 cases.

Rhode Island: Providence, Jan. 25-Feb. 1, 1 death.

South Carolina: Jan. 18-25, Charleston, 2 cases; Greenville, 1 case.

South Dakota: Sioux Falls, Jan. 24-Feb. 2, 4 cases.

Tennessee: Memphis, Jan. 25-Feb. 1, 12 cases.

Washington: Tacoma, Jan. 19-26, 3 cases.

Wisconsin: Green Bay, Jan. 24-Feb. 2, 10 cases; Milwaukee, Jan. 25-Feb. 1, 3 cases.

#### SMALLPOX—FOREIGN.

Brazil: Para, Nov. 1-Dec. 31, 25 cases, 2 deaths.

Colombia: Cartagena, Jan. 13-19, 2 deaths; Panama, Jan. 20-27, 25 cases.

France: Paris, Jan. 11-18, 7 deaths.

Great Britain: Bristol, Jan. 4-11, 1 case, 1 death; Liverpool, Jan. 11-18, 3 cases; London, Jan. 11-18, 877 cases, 60 deaths.

India: Bombay, Dec. 31-Jan. 7, 1 death; Karachi, Dec. 29-Jan. 5, 8 cases, 2 deaths; Madras, Dec. 14-20, 3 deaths.

Italy: Naples, Jan. 11-18, 15 cases, 3 deaths.

Russia: St. Petersburg, Jan. 4-11, 5 cases, 1 death.

Uruguay: Montevideo, Nov. 8-Dec. 7, 268 cases, 26 deaths.

#### YELLOW FEVER.

Brazil: Para, Oct. 1-Dec. 31, 24 deaths.

Dutch Guiana: Paramaribo, Jan. 9, 2 cases suspect.

Mexico: Vera Cruz, Jan. 18-25, 1 case.

#### CHOLERA.

India: Bombay, Dec. 31-Jan. 7, 1 death; Calcutta, Dec. 28-Jan. 4, 33 deaths; Madras, Dec. 14-20, 4 deaths.

#### PLAGUE.

China: Hongkong, Dec. 14-21, 1 case.

India: Bombay, Dec. 31-Jan. 7, 213 deaths; Calcutta, Dec. 28-Jan. 4, 22 deaths; Karachi, Dec. 29-Jan. 5, 31 cases, 26 deaths.

### THE HISTORY OF THE INVENTION AND OF THE DEVELOPMENT OF THE OPHTHALMOSCOPE.\*

HARRY FRIEDENWALD, M.D.  
BALTIMORE, MD.

The marvelous advance that modern medicine has made is due in great part to the invention of instruments of precision. They have lent delicacy and accuracy to our methods of examination and have opened new fields that were closed to our unaided senses.

When early in the last century Laennec invented the stethoscope, he gave us the means of discovering morbid processes within the body and thus revolutionized internal medicine. Helmholtz's invention of the ophthalmoscope did the same for ophthalmology. In both cases the field had long been cleared and there was no reason why the instrument should not have been invented earlier, but that in the one case it required the genius of Laennec and in the other the versatile and profoundly scientific talent of Helmholtz to lay bare simple facts which every tyro saw plainly after they had once been pointed out.

As the invention of the stethoscope enabled us to perceive deep-seated morbid processes by means of the sense of hearing, so the invention of the ophthalmoscope gave us the means of recognizing by the sense of sight the normal or abnormal conditions of the fundus of the eye which had been hidden from view during all the ages. Auscultation might have reached a high state of development without any instrumental aid, but no one could ever have seen the details of the fundus oculi without some instrument based upon the principles which Helmholtz discovered.

It is now fifty years since Helmholtz announced his invention in the unpretentious monograph which I here show. It is most fitting that this body representing ophthalmology in America should commemorate the jubilee, and show its grateful appreciation of the work of Helmholtz and of the value of his gift.

It is of special interest to us to take a glance at the gradual accumulation of facts and observations, the building stones which were needed before even a Helmholtz could rear his structure. The most important of these was the observation of the luminous appearance of the pupil. The ancients had observed this in the eyes of certain animals.<sup>1</sup>

The first mention of the observation in the human

eye was made in 1796 by Fermin, who found that the pupils of an Ethiopian albino were luminous. Other cases were published, as rare and curious during the first quarter of the 19th century. The statement was made that the light radiating from such eyes illumined the objects on which it fell and enabled the fortunate individual to read in the dark!

The bright yellow appearance of the pupils in certain forms of disease, first mentioned by Scarpa in 1816, was classically described by Beer in 1817 under the title of "Amaurotic Cat's Eye."

We find no mention of luminosity in other than albinotic or diseased eyes until 1837, when Behr observed it in a case of total irideremia and it was not until the forties that the observation was made on normal eyes.

It is interesting to learn the theories that were offered to explain these observations. First it was regarded as a phenomenon of phosphorescence; by some as the light absorbed during the day and given off at night, and later by others as the result of an internal activity similar to that of the fire-fly. It was described as varying with the seasons, with the age of the individual and with his nervous state. Electricity was also called upon to assist in explaining the luminosity of the eye. It was the "naked electricity emitted by the retina, for nowhere in the animal organism is the brain substance exposed to the naked eye as clearly as in the open interior of the eyeball" (Pallas, 1811). But Prevost in 1818 pointed out the true cause: it was the reflection of the light which entered the eye, and Gruithuisen about the same time came to a similar conclusion.

In 1821 Rudolphi added the observation that success of the experiment depended upon having the light thrown in, in a definite direction and that the eyes of the decapitated head of a cat were as easily made luminous as the living.

Esser in 1826 showed that such eyes shone even brighter than the living, because of the larger size of the pupil, and Johannes Mueller expressed the same view.

In 1836 Hasenstein showed that he could make the pupil luminous by compressing the eyeball in its antero-posterior diameter, and in 1845 Bruecke gave the correct explanation of the red color of the luminous pupil in that the light was reflected by the choroidal blood vessels.

In 1846 a most important communication was published by Cumming in the *Medico-Chirurgical Transactions*. He showed that every healthy human eye can be made luminous. The person is placed at a definite distance from a light, this distance varying with the intensity of the light, and the observer places himself close to the straight line between the course of light and the eye examined. He showed that the luminosity of the

\* At the Meeting at Atlantic City, Drs. Harry Friedenwald and Casey Wood were appointed a committee to arrange exercises and an historic exhibit for the St. Paul Meeting, to commemorate the 50th anniversary of the invention of the ophthalmoscope.

pupil varied with the intensity and the distance of the light and that when the distance was decreased to a few inches it vanished because the light is cut off by the head of the observer. He reported a number of cases in one of which only could he not produce the luminous appearance. In this case the pupils were very small. It was Cumming who first suggested and used this method for examination of the posterior portion of the eyeball, making the endeavor to draw conclusions concerning the retina as well as the media from the conditions of the reflex.

About this time Bruecke's attention was directed to this subject by accidentally observing a young man's eyes become luminous, and in 1847 he invented independently the same method as that of Cumming. He also mentioned an observation of Erlach, that eyes could be made luminous by the bright light reflected from his concave spherical spectacle glasses, a fact which Bruecke substantiated by experiments on others.

About the same time an instrument was constructed by Babbage, of calculating machine fame, which almost made this scientist take Helmholtz's place as the inventor of the ophthalmoscope. Almost! The account was not published until three years after Helmholtz's invention had been made and appeared in an article by Wharton-Jones<sup>2</sup> in which he reviewed Helmholtz's publication and several that appeared subsequently. He says: "It is but justice that I should here state, however, that seven years ago Mr. Babbage showed me the model of an instrument which he had contrived for the purpose of looking into the interior of the eye. It consisted of a bit of plain mirror, with the silvering scraped off at two or three small spots in the middle, fixed within a tube at such an angle that the rays of light falling on it through an opening in the side of the tube were reflected into the eye to be observed and to which one end of the tube was directed. The observer looked through the clear spots of the mirror from the other end. This ophthalmoscope of Mr. Babbage we shall see is in principle essentially the same as those of Epkens and Donders, of Coccius and of Meyerstein, which themselves are modifications of Helmholtz."

What a pity that Babbage did not devote a little more time to this invention! He could hardly have missed being the inventor of an instrument whose value is a thousand times greater than that of all the calculating machines ever invented.

To return a moment to another aspect I must point out that as early as 1704, Mery observed that the fundus of cats' eyes became distinctly visible when the animal was placed under water. LaHire explained this phenomenon five years later: "When a normal eye is in the air the rays of light issuing from a point in the fundus are so refracted that they leave the eye in parallel lines. For this reason we should be able to see the point in the fundus clearly, for parallel or almost parallel rays always produce a distinct perception in our eye; nevertheless, we do not see the object. On the other hand, when the eye is under water the rays leaving the eyeball diverge and in passing from the water into the air they are made to diverge still more. The result is that wherever we place our eye these divergent rays give us a clear picture of the point in the fundus from which they emerge." He does not attempt to explain the problem why parallel rays emerging from an eye exposed to the air can not be seen.

LaHire's profound statement was too advanced; others

receded from it and it required almost 150 years before the problem was solved.

In 1851<sup>3</sup> a little pamphlet was published by Helmholtz, then a young professor of anatomy and physiology in Königsberg, under the title of "*Beschreibung Eines Augen-Spiegels zur Untersuchung der Netzhaut im Lebenden Auge.*" In this he demonstrated the fundamental facts that *the rays pass out of the eye in the same lines in which they have entered and that they can be made to form a distinct image in an observer's eye.* He explains Cumming's and Bruecke's observations as being due to the fact that the eye is not exact focus for the light and thus rays pass out by lateral dispersion. But what was most important he added the *practical* to the *theoretical* and invented an instrument with which the details of the retina could be examined. He described the ophthalmoscopic appearance of the retina, calculated the enlargement under which it is seen, pointed out the value of the instrument as a measure of the refraction and of the accommodative changes of the eye. His short monograph was thorough and complete and gave into our hands a means of examination of which no one had yet dreamed. In his modest way Helmholtz thus prophesies its usefulness:

"I do not doubt, judging from what can be seen of the state of the healthy retina, that it will be possible to discern all its diseased conditions, so far as these, if seated in other transparent parts such as the cornea, would admit of diagnosis by the sense of sight. Distension or varicosity of the retinal vessels will be easily perceptible. Exudations in the retinal substance, or between the retina and choroid, will be seen precisely as in the cornea, by their brightness upon a dark ground.

Fibrinous exudations, usually much less transparent than the ocular media, will, when lying upon the fundus, considerably increase its reflection. I believe also that turbidity of the vitreous body will be determined with greatly increased ease and certainty. In brief, I do not consider it an overstrained expectation that all the morbid changes of the retina or of the vitreous body that have been found in the dead subject will admit of recognition in the living eye; an expectation that appears to promise the greatest progress in the hitherto incomplete pathology of the organ."

It will not be out of place to tell the story of the invention of the instrument in Helmholtz's words: "I was endeavoring to explain to my pupils the emission of reflected light from the eye, a discovery made by Bruecke, who would have invented the ophthalmoscope had he only asked himself how an optical image is formed by the light returning from the eye. In his research it was not necessary to ask it, but had he asked it, he was just the man to answer it as quickly as I did and to invent the instrument. I turned the problem over and over to ascertain the simplest way in which I could demonstrate the phenomenon to my students. It was also a reminiscence of my days of medical study that ophthalmologists had great trouble in dealing with certain cases of eye disease, then known as black cataract. The first model was constructed of pasteboard, eye lenses, and cover glasses used in the microscopic work. It was at first so difficult to use that I doubt if I should have persevered, unless I had felt that it must succeed; but in eight days I had the great joy of being the first who saw before him the living human retina."

How peculiarly applicable are the lines of Weir Mitchell:

How keen the mind-thrill of delight  
 When some new sun illumines our lessening night,  
 And problems, dark for many a weary year,  
 Shine, simply answered—luminous and clear.

#### THE HELMHOLTZ OPHTHALMOSCOPE.

This interesting instrument, of which there are five models in the exhibit, consists of a little metallic box with plates set at an angle which act as reflectors. In the back of the instrument correcting lenses were placed to neutralize the refractive and accommodative conditions of the eye examined and of the eye of the observer. In the early cases these lenses were all concave<sup>4</sup> and ranged from —12 in. to —6 in. which Helmholtz<sup>5</sup> says "suffice for all conditions of the accommodation." He himself usually used —10 in. spherical glass to examine normal eyes, and for high degrees of myopia he combined two concave glasses.

For the purpose it was invented, this instrument is optically perfect, and Helmholtz not only recognized all the possibilities of pathological discovery which it offered but he also saw the value that it possessed for the determination of the refractive condition of the eye examined.

"One can easily convince himself objectively with the ophthalmoscope of the presence and the degree of shortsightedness and of far-sightedness." His method consisted in having the observer first determine the concave glass required for examination of a normal eye and subtracting this constant from the glass required for the examination of other eyes, a method which we all use in teaching beginners.

No instrument used in medicine was destined to undergo a greater number of changes and modifications than the ophthalmoscope. In the same year in which Helmholtz's monograph appeared, Epkens constructed a plain silvered mirror with the silvering removed at a spot in the center.

#### RUETE'S OPHTHALMOSCOPE.

In 1852 Ruete<sup>6</sup> announced the invention of an ophthalmoscope by means of which the fundus was rendered visible in an inverted image by what has since been known as the indirect method. It is true that Helmholtz discussed the question of examining the fundus in this manner by means of convex spheric glasses placed between the observer and the observed eye, but he placed his lenses behind the ophthalmoscope, between the reflecting surface and the eye of the observer. After making careful and interesting calculations, he described that "in experiments with such lenses the proper position of the instrument for the examination of the retinal image was very much more difficult to find and to hold." Helmholtz himself therefore only used the direct method.

Ruete's instrument, which through the kindness of Dr. B. Joy Jeffries, I have the good fortune of being able to show in the exhibit, is most curious and interesting. As reflector, Ruete introduced a concave perforated mirror placed at a distance from the observed eye and he interposed between this mirror and the eye examined one or two spheric convex lenses.

Ruete therefore deserves the credit for having introduced a practical method for examining the inverted image of the retina and too great praise can not be bestowed upon him. Helmholtz himself said of it: "I consider the invention of his instrument an important advance in the examination of the fundus." In his article Ruete describes a few pathological cases exam-

ined by means of his instrument; these, so far as I am aware, are the first on record.

Ruete's paper soon called forth another from Helmholtz<sup>7</sup> in which he explained the theory of the indirect method and described his "simplest ophthalmoscope" which required nothing but a screen, a candle and a convex spheric lens.

The observer's head is placed close to the candle and shaded by a screen and the lens is held near the eye examined. This and Ruete's method he showed were practically identical. Helmholtz also mentioned an addition made to his original instrument by Rekoss, an instrument-maker of Königsberg. Rekoss placed two discs which had lenses inserted in their periphery in the instrument; by turning these the lens desired could be obtained. This device,<sup>8</sup> the Rekoss disc, has been used in most modifications of the instrument.

In 1853<sup>9</sup> Coccius invented an instrument which consisted of a plain mirror upon which the light was thrown through a convex spheric glass. The mirror and the lens were firmly attached to each other, but their distance from each other admitted of change. In this manner the plane mirror acted as a concave mirror of variable focus. (Several forms of this mirror are found in the exhibit.)

Eduard Jaeger<sup>10</sup> in 1854 modified the instrument of Helmholtz. The three plates of unsilvered glass were retained for the direct method, but these could be replaced by a concave silvered mirror for the inverted image; thus he made a combination of the Helmholtz and the Ruete instruments. In 1871 Dr. George Strawberry<sup>11</sup> of Philadelphia further modified this instrument by adding three Rekoss discs which were interchangeable.

We have now seen that plain and concave mirrors were used. In 1854 Zehender<sup>12</sup> used a convex mirror with a convex spheric glass attached in the same manner as that of Coccius. But this does not exhaust the mirrors used. Lenses were employed, both convex and concave and concavo-convex of varying strengths, which were silvered on one side and thus acted as both correcting lenses and mirrors. In the exhibit you will find several such mirrors made of silvered biconvex lenses and known as Burrow's<sup>13</sup> ophthalmoscopes. All of the instruments thus far mentioned are found in the exhibit.

Prisms were employed as mirrors by Ulrich, Froebelius, Meyerstein, Coccius and Zehender,<sup>14</sup> but I have been unable to obtain any of these forms.

A very simple ophthalmoscope was early invented by Liebreich, first in the form of a concave metallic mirror, later of perforated glass. You will find a long series of these in the exhibit. Liebreich also invented an instrument in which the various parts were fixed and the head of the patient likewise made stationary.<sup>15</sup>

Follin also constructed an instrument in which the mirror and the collecting lens were stationary—and Galezowski<sup>16</sup> invented one in which the lens and the mirror were placed at the two ends of a telescopic tube. The stationary instruments were especially intended as demonstrating ophthalmoscopes. Special demonstrating ophthalmoscopes were also constructed by Schweigger,<sup>17</sup> in which the rays returning through the opening in the mirror were in part allowed to proceed to the observer's eye, in part deflected by a prism to the eye of another to whom the demonstration was to be made. Graefe and Peppmueller<sup>18</sup> described an instrument for the same purpose in which a small piece of mirrored glass was placed on the mirror at the side of the

opening.<sup>19</sup> All of these instruments are found in our exhibit. We have also a Schoeler<sup>20</sup> demonstrating ophthalmoscope in which a minute mirror is placed obliquely behind the opening of the ophthalmoscopic mirror.

Numerous attempts were made to obtain a binocular view of the fundus. A number of modifications of Giraud Teulon's binocular ophthalmoscopes are found in our exhibit.

Of the half dozen electric light ophthalmoscopes that have been invented I am only able to present one model, that of Schweigger.

#### REFRACTION OPHTHALMOSCOPES.

The first to invent a refraction ophthalmoscope was Helmholtz when he added the Rekoss discs to his instrument. This same device has been used in numerous forms of instruments.

No one has contributed more to perfecting this than our fellow-countryman, Loring. I am very fortunate in being able to show the various steps which led up to the present instrument, which is known to you all. Loring first inserted three interchangeable discs behind the mirror, later he placed all the lenses in one disc making a double circle of glasses and by moving the disc up and down he could place either circle before the eye. Finally he secured all the strengths necessary by means of a single disc and a super-added segment. Wadsworth of Boston first suggested a mirror set obliquely before the observer, so as to enable the latter to look directly through the lenses and not at an angle. This instrument we have in our exhibit, loaned by Dr. Wadsworth. Loring adapted the same modification in an ingenious way by cutting off a segment at one edge of his round mirror and still later he found that he was able to take off a segment on each side and thus came about the modern Loring tilting mirror.

Another method of placing a great number of lenses in an instrument was invented by Cooper of London. He formed a long chain of lenses sliding in a groove. Morton modified this and his instrument is also in the exhibit.

A number of instruments have the correcting lenses arranged in a line and placed in a narrow metal plate which slides in a groove. Several are in the exhibit.

I should like to devote a little time to the consideration of skiascopy but time will not permit, and I shall only call your attention to a number of varied mirrors for this purpose to be found in the exhibit. Nor dare I spend any time on ophthalmoscopic photography.

The days of invention of new ophthalmoscopes are not over. In 1900 two important instruments were invented, one a demonstration ophthalmoscope by Thorner, the other an electric light ophthalmoscope by Oscar Wolff. I regret that we were unable to obtain these for the exhibit.

It would have been impossible to make this collection complete. But a sufficient variety is shown in the 140 instruments making up the exhibit to afford a good demonstration of the development of the ophthalmoscope and of its many modifications. All have been collected in this country, and I trust that the section will agree with me in urging the Surgeon-General of the United States to arrange a permanent historic exhibit at the Army and Navy Museum in Washington. Many of these instruments are already very rare and will otherwise be lost in a few years. I feel confident that many who have loaned their instruments to us will be willing to loan them, and some, perhaps, to give them, to the Surgeon-General's Museum.

In conclusion I desire to give thanks to Dr. Casey A. Wood, my colleague on the committee and to the following gentlemen who have kindly loaned their instruments:

#### LOANERS.

Dr. B. Joy Jeffries, of Boston (eight instruments).  
Dr. Charles H. Williams, of Boston (eight).  
Dr. Hasket Derby, of Boston (six).  
Dr. D. W. Hunter, of New York (six from the collection of the late Dr. Noyes).  
Drs. F. M. Chisolm and Herbert Harlan, of Baltimore (five).  
Dr. Casey A. Wood, of Chicago (four).  
Dr. William Thomson, of Philadelphia (four).  
Dr. Conrad Behrens, of Philadelphia, Wills Eye Hospital (four).  
Dr. Webster Fox, of Philadelphia (three).  
Dr. Charles H. May, of New York (two).  
Dr. Lucian Howe, of Buffalo (two).  
Dr. Jackson, of Denver (two).  
Dr. Dudley Reynolds, of Louisville (two).  
Dr. Callan, of New York (two).  
Dr. Edward Morrow, of Canton, Ohio (one and Montleja's Atlas).  
Dr. Flemming Carrow, of Ann Arbor, Mich. (one).  
Dr. C. Barck, St. Louis (one).  
Dr. Hermon Thomas, of Philadelphia (one).  
Dr. Alex. Stirling, of Atlanta, Ga. (one).  
Dr. K. Koeller, of Pittsburg (one).  
Dr. C. M. Culver, of Albany, N. Y. (one).  
Dr. Samuel D. Risley, of Philadelphia (one).  
Dr. Shallus, of Philadelphia (one).  
Dr. Jessop, of Philadelphia (one).  
Dr. Zimmerman, of Philadelphia (one).  
Dr. G. Edgar Dean, of Scranton, Pa. (one).  
Dr. William C. Banc, of Denver, Colo. (one).  
Dr. H. B. Young, of Burlington, Iowa (one).  
Surgeon-General's Museum, through Dr. Caloni DeWitt (one).  
Dr. Brown Pusey (seven), and Chambers, Inskeep & Co., Chicago.

I feel that Messrs. Tiemann & Co., of New York, Messrs. Benschur and Holmes, of Philadelphia, and Mr. Alex. Shaw, successor of Mr. H. W. Hunter, of New York, and Mr. E. B. Meyrowitz, of New York, deserve our special gratitude for the interest and pains they have taken in collecting old instruments. Messrs. Tiemann & Co. sent twelve instruments, Messrs. Benschur & Holmes collected fourteen and added four more from their stock, and Mr. Alex. Shaw sent two made by Hunter.

#### REFERENCES.

#### HERMANN VON HELMHOLTZ—THE INVENTOR OF THE OPHTHALMOSCOPE.\*

CASEY A. WOOD, M.D.  
CHICAGO.

*Formals im Leben ehrten wir dich, wie einen der Goetter,  
Nun du todt bist, so herrscht über die Geister dein Geist.*

Quite apart from the interest that is naturally excited by the life-story of the great scientist who invented the instrument that revolutionized the science and art of ophthalmology, there are, at least, two reasons why this gathering should be especially interested in the life of Hermann Ludwig Ferdinand Von Helmholtz. In the first place it was as a student and practitioner of medicine that he entered upon those studies that carried his name and spread his fame throughout the world of science. Then, in the second place, there coursed in his

\* At the Meeting at Atlantic City, Drs. Harry Friedenwald and Casey Wood were appointed a committee to arrange exercises and an historic exhibit for the St. Paul Meeting, to commemorate the 50th anniversary of the invention of the ophthalmoscope.

veins the bluest of American blood. His mother was the daughter of a Hanoverian artillery officer named Penne, a direct descendant of William Penn. It is more than possible that the calm, thoughtful spirit which distinguished all the actions of this truly great man was largely due to the Quaker element in his character. He was born at Potsdam, near Berlin, on August 31, 1821—the son of Ferdinand Helmholtz, a teacher in the gymnasium, and a man of unusual intelligence and culture. The subject of this sketch had, on the whole, a quiet uneventful life. He was not given to talking much about himself even to his most intimate friends, although he occasionally broke through his natural reserve in this respect. In 1891, when he replied to a toast in honor of his seventieth birthday, he opened his heart to his hearers, and we are indebted to this festive occasion for much that we know of the private life and opinions of the speaker. Although by no means robust as a boy, his mind always showed great activity. He tells us that it was while playing with a set of wooden blocks that his attention was first drawn to mathematical problems. He had the good fortune to possess a father who encouraged him in the study of general literature, and although he acquired languages with great difficulty, he was very fond of poetry, and at an early age read Homer, Virgil and even Arabic tales and verse. He also had the advantage of listening to the discussions, philosophical and other, that took place in his father's house, and made an early acquaintance with the metaphysics of Kant and Fichte. As he grew older he threw off the physical disabilities that affected his early youth and began to take long walks through the country, first in the beautiful environs of Potsdam and later through Europe, that formed, with the delightful and profitable companionship of his father and other friends, one of the most fruitful experiences of his whole life. Du Bois Reymond asserts that these excursions, as well as his later mountaineering experiences in the Alps, had for him something more than a hygienic value. We know that the solution of many a problem came to him while engaged in these holiday recreations. For example, it was while watching the troubled sea at Cap d'Antibes that he measured the velocity of the wind with an anemometer, counted the number of waves on a given surface of sea and thus obtained the necessary data for his conclusions on the relation of wind velocity to wave lengths.

Helmholtz was soon attracted by the study of physics as opposed to mere abstract investigation of algebra, geometry and trigonometry, and although he regarded mathematics as a *sine qua non* in physical research, he was essentially a student of physical phenomena. If there is one thing that characterizes his life-work it is a passionate desire to know things as they really are and to study them especially from their physical side. This zeal became more pronounced the older he grew, and we know that as an experimenter he had no superior and few equals. While his class in the gymnasium was reading Greek and Latin authors, generally regarded as a severe task by the young physicist, he was surreptitiously working out optical problems and illustrating the passage of light rays through the telescope. His father was a man of small means and could not afford to purchase expensive apparatus for his son; hence the latter was obliged to utilize in his primitive investigations spectacle glasses and a small lens used for examining botanical specimens.

In 1838 he left the gymnasium to attend the University at Berlin with the following prophetic testi-

monial from the rector: "His exceptionally calm and reserved disposition is combined with great intellectual enthusiasm. In it we recognize an excellent combination of clear and prudent understanding and deep good nature. His manners bear witness to a carefully preserved, exceptionally pure, and genuine childlike innocence. These peculiarities, along with the richness and power of his mental development, give an agreeable and captivating impression, and justify the hope that such a ground-soil of intellectual life will only bring forth the best of fruits."

It is difficult to realize from what we know of his maturer years, that Helmholtz had no extensive training in mathematics during his youth. It appears, however, that he recognized the necessity of a thorough knowledge of this branch as an adjunct to his study of physics, and he applied himself to it with the quiet persistence that also marked his successful acquirement of foreign languages. Those of us who remember the speech he made at the dinner in his honor at Chicago in 1893 will scarcely believe that he was not a ready linguist.

Helmholtz was one of four children, and the difficulties which Ferdinand Helmholtz encountered in supporting his family made it necessary that Hermann should earn his own livelihood at an early age. He was advised to study medicine and, with the assistance of a relative, Surgeon-General Mursinna, in 1838, entered as a bursar the Royal Medical-Chirurgical Friedrich-Wilhelm Institute in Berlin. Here a free medical education was given the student on condition that he afterwards become a surgeon in the Prussian army. He attended the usual courses in the Medical Department of Berlin University, was attached for a time to the Charité Hospital, finally obtained his diploma and became an army surgeon.

In a lecture delivered in 1877 on "Thought in Medicine," a lecture which I respectfully commend to the attention of all who have not carefully read it, he speaks of this period of his life. "My own original inclination," said he, "was towards physics; external circumstances obliged me to commence the study of medicine. It had, however, been the custom of a former time to combine the study of medicine with that of the natural sciences, and whatever in this was compulsory I must consider fortunate; not merely that I entered medicine at a time in which any one who was even moderately at home in physical considerations found a virgin field for cultivation, but I consider the study of medicine to have been that training which preached more impressively and more convincingly than any other could have done, the everlasting principles of all scientific work; principles which are so simple and yet are ever forgotten again; so clear and yet always so hidden by a deceptive veil."

It was during this time that he became the associate—the fortunate associate—of a number of other students in Berlin whose names are now and ever will be as household words to the medical man—Johannes Müller, Du Bois Reymond (an old school friend) Brücke, Gustav Magnus, Kirchhoff, Virchow and many others of that brilliant group who, with himself, became the founders of the Berlin Physical Society. The main function of this association was, as you know, to consider physiological and other problems from the physical rather than from the metaphysical side.

While engaged in his usual medical duties, Helmholtz had, as he tells us in "Thought in Medicine," an attack of typhoid fever, for which he was treated gratuitously in the Charité. As his allowance for board was in the

meantime continued, he found himself at the end of his convalescence in the possession of a small sum of money, which he invested in a compound microscope. Do not imagine for a moment that this was one of those expensive and effective instruments with which every medical college is nowadays liberally supplied. In Helmholtz's youth microscopes were rare, and microscopical research by the student still rarer. Yet with this primitive instrument he demonstrated in the nervous ganglia of leeches that the nerve fiber or its axis cylinder always originates from the polar process of the nerve cell, and this investigation formed the basis of that inaugural thesis (*De Fabrica systematis nervosi Evertibratorum*) which at the age of 21 he presented on graduation. Sometimes we are led to believe, and our splendidly equipped laboratories in a certain sense reflect this belief, that it is a particular kind of tool that plays the important part in the work of original research, without a reckoning of the workman, just as occasionally we lose sight of the "man behind the gun" in estimating the probable value of the firearm.

It is not the purpose of this paper to follow, from these beginnings, Helmholtz's triumphant progress through the world of physical science. Even a short account of the additions which he made to our knowledge of chemistry, physiology, mechanics, hydrodynamics, optics, acoustics, electricity, color and mathematical physics generally, not to mention their practical application in the invention of instruments of precision, would more than occupy the time at my disposal. McKendrick says of him that from 1842, when his thesis was published at 21 years of age, until 1894, when he died, papers flowed from his pen in almost uninterrupted succession. With the exception of the year 1849 he always published at least one important contribution, so that no fewer than 217 distinct papers and books represent his labors. He lived in Berlin from 1842 to 1847, when he became, at the age of 29, professor of physiology at Königsberg. There he remained until his 35th year (in 1856) when he was promoted to the chair of physiology in Bonn. In 1859 he was made professor of physiology in Heidelberg. When 50 years old he was called to occupy the chair of physics in Berlin, and there he remained until his death. His early years in Berlin were occupied as assistant physician at the Charité and as assistant surgeon in the Red Hussars regiment at Potsdam. He never had a private medical practice; indeed, we know that every moment he could spare from his public medical duties was devoted to physical science. Eventually Alexander von Humboldt, recognizing his capacity, asked that he be relieved from all military duty and obtained for him several minor positions where he could devote most of his time to the study of anatomy and physiology.

As a student, some fifteen years ago, in the Physiological Institute of Berlin University, it was my good fortune to have been thrown in contact with many of the teachers that have made that institution famous—with Helmholtz, Du Bois Reymond, König, Fritsch, Gad and others of the same school. No one could fail to be impressed by the spirit of earnestness, simplicity and devotion to science for its own sake that characterized the labors of these brilliant investigators. I can not refrain from mentioning a circumstance illustrative of this idea, that is familiar to most of you. At intervals the students and teachers of the Institute were invited for a social gathering to some convenient place where all topics imaginable—but especially scientific subjects—were discussed. One in particular I remember at which Helmholtz and Du Bois Reymond were present. It was called, if I recollect aright, in the invitation posted at the Institute, *eine Bier-microscopische Versammlung*, a term fairly descriptive of the entertainment, because we wore our everyday clothes, drank beer, ate sandwiches, examined microscopical slides, listened to animated scientific discussion and enjoyed what then, and what still seems to me to be the very best society in Germany. Probably a corresponding entertainment would be represented in some other countries by an orchestra behind a row of palms, floral decorations, ten courses of indigestible imitations of French cooking and all the "guests" in their "dress" suits and on their finest behavior. Whenever I attend a medical "banquet" I can not help breathing a sigh for the simple (primitive, if you will) social joys of the German University.

Something, by the way, ought to be here said about the important work which Helmholtz did in perfecting the microscope—in supplementing the labors of Abbé of Jena in this direction. Among many other things he showed us how to find and measure the angle of aperture, and he proved that because of the light-dispersion at the margins of minute objects none of these can be seen that are of a smaller diameter than  $1/5000$  of a millimeter.

In some form or other and at some time or other the great problems relating to the forces that play in us and about us occupy one's attention, and Helmholtz endeavored to solve some of these great questions (so far as physical research can ever solve them) in his famous essay, "Ueber die Erhaltung der Kraft." Although the principle of the conservation of energy is now so universally accepted as to be considered almost axiomatic, and though it was dimly realized by Newton, Descartes and others, this paper of Helmholtz, read before the Physical Society, aroused much criticism, and it was actually refused publication in the well-known *Annalen* of Poggendorff on account of its doubtful value!

In 1849, when Helmholtz was 29 years of age, he married Frl. Olgo von Velten of Potsdam, who died at Heidelberg in 1859. He had by this marriage two children, a son, an engineer now living in Munich, and a daughter who became the wife of Professor Branco, the geologist.

In 1861 he entered upon a second marriage with Frl. Anna von Mohl, a lady belonging to a Wurtemberg family of high social position, who also bore him two children, a son and a daughter. Robert, the elder, died in 1889 after he had given evidence of having inherited many of the mental qualities of his distinguished father. It is said that Helmholtz never entirely recovered from this blow. The daughter married the son of Werner von Siemens, the well-known electrician.

Helmholtz was an accomplished musician and no mean vocalist. The pleasures of congenial society, with music, formed his principal recreation. It may be said, in passing, that the splendid grand piano upon which he loved to play was presented to him by the house of Steinway of New York in recognition of his services to music.

The answer which the devotee of pure science is likely to give to the objection raised by the so-called "practical" man that there is little value to be attached to merely theoretical investigations, might take the form of a reference to the invention of the ophthalmoscope which we may consider the most beneficial of all the works of Helmholtz. We have the testimony of the inventor himself that its origin was the outcome of a desire to exhibit "purely physiological phenomenon" to his students in Königsberg. Its application in the diagnosis and treat-

ment of disease was really an after-thought. As you are well aware, and as the labors of my colleague have enabled us so well to appreciate in the fine exhibits his industry has set before us, the first ophthalmoscope was a very crude instrument. For that matter, so also were the forerunners of the modern myograph, phakoscope and ophthalmometer, all invented at Königsberg by this versatile genius. As a further example of Helmholtz's universal study of men and things, Du Bois Reymond tells us that as a recreation he was in the habit of watching through a telescope the walking methods of the Königsberg citizens so that he might compare his observations of human locomotion with those of Weber.

In Bonn he wrote the well-known monograph on the ossicles and membrana tympani that forms so large a portion of modern physiological acoustics, just as his researches in physiological optics contributed so much to our knowledge of optical problems.

In 1864 he delivered the well-known Croonian lecture "On the Normal Motions of the Human Eye in Relation to Binocular Vision." His studies of the horopter and stereoscopic vision led to the invention of the telestereoscope which, as you well know, is an instrument where two images of distant objects are seen as if the foveæ were much more widely separated than normal.

Helmholtz was a sufferer from a form of hay fever that greatly interfered with his enjoyment of the *Ferienzeit*. As no one appeared to be able to relieve him, and as little was then known of the etiology of this strange disease, he, with his usual energy, attempted to discover its cause. A full account of these researches will be found in the 46th volume (1869), page 67, of Virchow's Archiv in an article by Professor C. Binz of Bonn, entitled "Pharmakologische Studien ueber Chinin." Having read the experiments of Binz with quinia sulphate on the organisms supposed to be responsible for the symptoms, Helmholtz used a nasal wash (1:800) of this remedy for four or five years and finally announced himself as cured. The following account of the attacks, their etiology as the sufferer himself worked it out, and the means he adopted for their cure, show what an admirable clinician he might have made. The English account is given in *Nature*, vol. x, page 26,

and is entitled "An Experimental Observation on Hay Fever," being a letter to Professor Tyndall from Professor C. Binz in Bonn, and forwarded by the former for publication.

"I have suffered as well as I can remember since the year 1847 from the peculiar catarrh called by the English 'hay fever,' the specialty of which consists in its attacking its victims regularly in the hay season (myself between May 20 and the end of June), that it ceases in the cooler weather, but on the other hand quickly reaches a great intensity if the patients expose themselves to heat or sunshine. An extraordinary violent sneezing then sets in, and a strongly corrosive thin discharge with much epithelium is thrown off. This increases after a few hours to a painful inflammation of the mucous mem-

brane and of the outside of the nose, and excites fever, with severe headache and great depression if the patient can not withdraw himself from the heat and the sunshine. In a cool room, however, these symptoms vanish as quickly as they come on, and there then only remains for a few days a lessened discharge and soreness, as if caused by the loss of epithelium. I remark, by the way, that in all my other years I had very little tendency to catarrh or catching cold, while the hay fever has never failed, during the twenty-one years of which I have spoken, and has never attacked me earlier or later in the year than the time named.

"The curious dependence of the disease on the season of the year suggested to me the thought that organisms might be the origin of the mischief. In examining the secretions I repeatedly found in the

PROF. H. VON HELMHOLTZ.

last five years certain vibrio-like bodies in it which at other times I could not observe in my nasal secretions. They are very small and can only be recognized with the immersion lens of a good Hartnack microscope.

"It is characteristic of the common isolated single joints that they contain four nuclei in a row, of which two pairs are more closely united. The length of the joints is 0.004 mm. Upon the warm objective-stage they move with moderate rapidity, partly in mere vibration, partly slowly backward and forward in the direction of their long axis; in lower temperatures they are inactive. Occasionally one finds them arranged in rows upon each other or in branching series. Observed some days in the

moist chamber they vegetate and appear somewhat larger and more conspicuous than immediately after their excretion. It is to be noted that only that kind of secretion contains them which is expelled by violent sneezings; that which drops away slowly does not contain any. They stick tenaciously enough in the lower cavities and recesses of the nose. I made a neutral solution of sulphate of quinin (1 to 800) which produced moderate irritation of the nasal mucous membrane. I then lay flat on my back, keeping my head very low, and poured with a pipette about 4 c.c. into both nostrils. Then I turned my head about in order to let the fluid flow in all directions. The desired effect was obtained immediately and remained for some hours so that it was sufficient to repeat the treatment only three times daily. I then found no vibrios in the secretion. After continuing this treatment for some days the symptoms disappeared completely, but if I leave off they return till toward the end of June."

Helmholtz's experiments began in the summer of 1867 and in 1872 he told Binz that his fever was quite cured and that several others had, by his advice, tried the same treatment with success.

Although we now have reason to believe from the observations of Blakely, Bostock and Bosworth that true hay fever is the result of the irritation set up by the pollen of certain flowering plants in individuals having a neurotic idiosyncrasy against them and that the organisms seen by Helmholtz were probably fragments of spores containing the fovilla of the pollen cells the clinical observations were accurate, the description of the disease eminently truthful, and the methods of examination were in accord with the teachings of modern science.

In 1877 Werner von Siemens founded the Physico-Technical Institute at Berlin, and Helmholtz, his lifelong friend, was chosen as its first Director. This position furnished him with some rest from teaching, but he still continued to deliver lectures twice a week in the University.

Five years after the demise of his son, Helmholtz sustained a further loss in the death of his favorite pupil, Heinrich Hertz, best known as the discoverer of electromagnetic or "Hertzian" waves. We may understand something of his grief from the following words which Helmholtz wrote but a few months before his own death: "The news of the death of this favorite of genius was a severe shock to all who recognize the development of the individual, both as regards mental capacity and the victory of the soul over the passions and opposing powers of nature. Endowed with the rarest gifts of mind and character, he has in his short life reaped a harvest in a field in which many of the most talented of his scientific brethren had labored in vain. In classical times his death would have been regarded as a sacrifice to the envy of the gods. Nature and fate co-operated in his development. In him we found all the qualities required for the solution of the hardest problems in science. . . . Heinrich Hertz appeared to be predestined to disclose new vistas into the unpenetrated depths of nature; but all these hopes were crushed by the insidious disease which slowly and unceasingly crept on until it destroyed the life we esteemed so valuable. I myself deeply feel the loss, as I have always looked on Hertz as the one of all my students who had entered into the innermost circle of my scientific thoughts, and the one in whose ultimate development and success I dared to place my surest hopes."

In 1894, the year of his death, appeared a new edition

of his *opus magnum*, the "Handbuch der Physiologischen Optik," a fitting crown to a long and successful life.

There is a matter to which the particular attention of this audience may well be drawn and that was the habit of Helmholtz to deliver popular lectures. Here was a man whose whole time was occupied in considering the most abstruse problems, whose every day teaching involved the use of terms intelligible only to minds with a special training, and yet he did not consider it outside his province to lay before the public the results of his own scientific experience and that of others. When Tyndall's lectures were published in German, Helmholtz wrote the preface and maintained that such popular presentations of scientific subjects were calculated to stimulate thought and to awaken an interest in scientific work. There can be no doubt but that his own public explanations of the phenomena of sight, of hearing, of the theories of music, of color and of the art of painting, may serve as models for popular lectures of all sorts. One may venture the assertion that medical topics discussed before public audiences in a tactful manner are not only useful in combating many ignorant ideas entertained by otherwise intelligent people, but they go a long way towards preserving these same persons from the machinations of the charlatans and panacea-vendors that infest the community. Do we not owe it to the public who, in a sense, are our medical wards, to provide them with authoritative teaching in physiology and pathology? If the elementary mysteries of biology and pathology are not publicly expounded by worthy representatives of the medical profession, it is no great wonder that the laity investigate them, to their hurt, elsewhere.

Reference has already been made to the mountaineering expeditions of Helmholtz. These strongly remind one of Tyndall. If one reads, first, the Helmholtz lecture on "*Eis und Gletscher*" and then Tyndall's "Glaciers of the Alps," or his "Forms of Water," he will surely feel that they were written by the same kind of man in an atmosphere that stimulated while it satisfied not only the inquiry into material, but into those immaterial things that both approached with a reserve tintured by reverence.

Honors of all kinds flowed in on Helmholtz during the latter part of his life. He was ennobled by the Emperor William I, and the present monarch sent him an autograph letter on the celebration of his 70th birthday. This event was considered not only of national but of international importance. The Kings of Sweden and Italy, the Grand Duke of Baden and the President of the French Republic, conferred upon him the insignia of various orders. He was the recipient of many university degrees, while academies and learned societies the world over sent congratulatory addresses. A Helmholtz medal, to be awarded for distinguished services to science, was struck in his honor. At a banquet shortly afterwards, Helmholtz had the pleasure of presenting the first medal to his friend, Du Bois Reymond, after a speech so characteristic of the man that I cannot refrain from quoting a portion of it:

"It is the greatest honor men of science could pay to me to connect my name with this medal, which will stamp the progress of science in future times. Science, to modern humanity, proclaims peace. The scientific man does not work for his own welfare, but for that of his nation, and for the whole of humanity, especially for those who are sufficiently educated to enjoy the fruits of science. You desire to associate my name with this medal, and to hold me up to coming generations as an

example of an investigator. I waver between a feeling of joy and a feeling of grave responsibility. I have a proud joy that the result of my thoughts is to work on to future generations far beyond my individual life. You will also understand that as a father cares for his offspring, and endeavors to help them, so I have also a love for the children of my thought. These contain the best of my convictions; I lay upon them the utmost stress; and I rejoice if the further development of science is to be in their direction. But the doubt may arise, whether my own ideals are not too narrow, and my principles sometimes too imperfect, for the wants of humanity in all time. If so, I hope the awarders of this medal in the future will not confine themselves to what I have accomplished, but I should like to wave on high the one banner on which are inscribed the words, that the purpose of science is to comprehend reality and the play of phenomena as regulated by law."

As you know, in 1893 he visited the Columbian Exposition, and afterwards made a tour over a part of the United States and Canada. On the return journey, just before landing at Hamburg, he had an attack of vertigo, and fell down the ship's companion-way. He received a severe scalp wound and suffered a concussion of the brain. This was followed in July, 1894, by a cerebral hemorrhage. He lingered two months longer, dying September 8, 1894, in his 73d year.

From personal acquaintance and from portraits we all know Helmholtz's appearance. He had a well-knit, erect frame, a quiet, graceful carriage, and a fine, well-developed face and head. Although his manner was reserved and dignified, he was always kind and courteous.

Of Helmholtz's attitude toward religion nothing definite can be said. Like Darwin, he considered religious questions so purely personal that he rarely mentioned them even to intimate friends. Perhaps, with Spinoza—another philosopher having affiliations with the ophthalmic art—he felt that the free man deliberates not upon matters of death or of after-death, but on the problems of everyday life. In any event, we have chiefly to deal with the achievements of a useful, noble and pure career, and in so far as we strive to imitate such a master do we surely keep his memory green.

## A FEW PERSONAL RECOLLECTIONS OF HELMHOLTZ.

HERMANN KNAPP, M.D.  
NEW YORK CITY.

The writer had the great privilege of being a pupil of Helmholtz, living eight years next door to him, at Heidelberg, seeing him almost every day. It gives me great pleasure to furnish some personal notes about Helmholtz's character, his working methods, industry, etc.

His working methods, from my first interview with him, aroused my admiration, by their directness. I presented myself in his laboratory without any introduction. He asked me what I wanted to do. I said I wanted to study ophthalmology, and my particular object was to drill myself in physiological optics, under assistance I could not obtain in Berlin.

"Where do you wish to begin your work?" I said: "I would like to begin at a certain problem in your paper on accommodation, of which I can not find a solution." He replied: "Sit down and let us see." I showed him the place, and told him that I was unable, with my knowledge of trigonometry, to reach a solution to which he had arrived at, without having given his readers the

benefit of a demonstration. It was about a year after the celebrated paper had been published. He began to calculate and got puzzled. He began a second and a third time, with the same result. Upon the fourth attempt he handed me the paper and said: "This seems to be the way in which you may find the solution."

Later on, when I was in the midst of my optical studies, I was surprised that a man, so original and deep as Helmholtz, was a believer in authority. I told him that in the study of Thomas Young's "Mechanism of the Eye" I thought I had found a mistake in a demonstration. He looked at the problem and its solution and said: "That seems wrong to me, too," but he added: "I advise you to go over the subject again as carefully as you can, for what Thomas Young has asserted has usually been correct." I followed his advice and found that not Thomas Young but I was in error.

Helmholtz was an independent, methodical, and persistent thinker. When he received a paper on a new problem he used to read only the first pages containing the question, then he laid the paper aside, and tried to find the solution himself. If it agreed with the author's solution he looked the book over to find whether the demonstration of the author differed from his own. If his solution disagreed with the author's he began his independent demonstration anew. You see what a wonderful self-education this habit must have been and how resourceful it must have made his mind. Helmholtz, like Thomas Young, had not received a classical education in mathematics. Both men were original in their demonstrations. His father was professor of mathematics, but the son studied medicine in the military school of Berlin. From his later works it would appear that he must have had an extensive library. That was not so at all. Professor Kirchhoff told me that his library was very small, but he had the wonderful gift of being able to select the best books, and these he studied carefully. "He always went his own way, which we school mathematicians could frequently follow with difficulty, and besides," Kirchhoff said, "when in a physical problem Helmholtz finds that the structure of the best mathematical treatise is too low for his purpose, he builds another story on it himself."

How often have I admired the harmony and efficiency of his working methods. He never undertook an investigation if the problem, on mature consideration of its nature and estimation of his own strength, did not promise a solution. This forethought spared him many a disappointment, and gave him the greatest return for his time and labor.

With regard to discoveries and inventions he was of opinion that most men failed to accomplish what they aimed at not by lack of ability and intellect, but by laziness, i. e., abandoning the subject before they had pushed it to the end of their thinking.

Apart from all these excellent qualities, I should not forget to mention that he also possessed that quality without which the best minds will not accomplish a great deal; I mean the trivial quality of industry. How often have I looked up to him standing before his desk at 11 at night when I returned from some entertainment. He was a judicious and untiring worker; he did all his work himself, not as is the custom nowadays—to let other people work for him. He had no assistant in his scientific work, not even an amanuensis.

As to his character, I can speak only with the highest praise. His was a true and noble nature. He was silent and distant in conversing with people that were selfish, vain and frivolous, but kind and courteous to all that

were unassuming and honest. He would explain to a lady physical and philosophical problems of an obscure nature animatedly if he saw that she took a real interest in them. With his laboratory students he was very generous; he gave them a great deal of his time, all the advice and help that could benefit them, and he would not let them have "all work and no play." Every Saturday afternoon we walked together through the beautiful country about Heidelberg, taking supper at some village on the Neckar or in the mountains. He loved music, literature, and art. He took a lively interest in everything that promised progress. On the excursions with his pupils and his friends he was a jovial companion, and happy to see everybody else happy. In his character he was frank and honest, never stooping to a shadow of untruth, however plausible the excuse for it might appear to be. He was a man, noble, great, and true.

## THE CONTRIBUTIONS OF HELMHOLTZ TO PHYSIOLOGY AND PSYCHOLOGY.

WINFIELD S. HALL, Ph.D., M.D.

Professor of Physiology, Northwestern University Medical School, CHICAGO.

### PHYSIOLOGY.

Physiology is an experimental science. The problems of physiology are problems of physics or of chemistry. Physiology thus becomes a superstructural science based upon anatomy, physics and chemistry. One who would solve the physical problems of physiology would also require a good working knowledge of mathematics. At the time Helmholtz undertook the solution of physical problems of physiology he was probably the best equipped man living, in the fundamental subjects above mentioned. For about ten years of his professorial life he was professor of anatomy and physiology. His foundation in anatomy was thus extended and elaborated far beyond that which most physiologists possessed. He was associated in his early studies with physicists and mathematicians so that his knowledge of physics and mathematics was also far beyond that of other physiologists of his time. We see in Helmholtz, then, a man in whom the circumstances of his early training and early professional life conspired to produce the best conditions for effective work. At the time he was a student in the University of Berlin, Johannes Mueller was professor of physiology and Gustav Magnus was professor of physics. Associated with him as pupils of one or the other of these great men were Du Bois Reymond, Virchow, Bruecke, Classius, Kirchhoff, Quincke, Seimens, Tyndall, and Wiedemann. It is said of Mueller that he "gave a great impetus to the movement that had already been begun in Germany in the direction of the investigation of biological problems by the methods of physical and chemical science." Helmholtz said of Mueller: "When one comes into contact with a man of his rank his spiritual scale is changed for life." There can be little doubt that Johannes Mueller's indefatigable search for truth and his enthusiastic demonstration of it when he had found it, profoundly impressed this group of disciples who were destined to reconstruct the whole field of experimental science.

Helmholtz's graduating thesis from the Medical Department of Berlin University was an anatomical one "On the Structure of the Nervous System of the Invertebrates" (*De Fabrica Systematis Nervosi Invertebratorum*). In this work he succeeded in establishing the

fact that the nerve fibers were branches of nerve cells, the ganglia of the crayfish serving as material for demonstration. The microscope which he used, though a very crude instrument, was one which he had bought from savings of his allowance accumulated at a time when he was confined to the wards of a charity hospital with typhoid fever.

Very soon after Helmholtz graduated from the medical school he took up the problem of *animal heat*, devising a triple thermo-electric junction of iron and German silver, which he bent into the form of needles that could be inserted into the muscles of the frog. With the help of these thermo-electric needles he was able to detect a change of temperature as small as .001 of a degree centigrade. He determined that one contraction of a frog's muscle produced from .001 to .005 of a degree while tetanus of the same muscle lasting from two to three minutes caused a rise in temperature of from .014 to .018 of a degree. With the help of calorimeter experiments Helmholtz determined that the heat given off from the body is less than the heat which should be given off to the calorimeter during the combustion of the same amount of food consumed in the body in a given time. From this he inferred that the food undergoes incomplete combustion within the animal body. Some time later it was found that the nitrogenous foods are completely burned outside of the body while they are reduced within the body from the proteid level to the urea level, thus giving up only about five-sevenths of the total heat represented by the food. Helmholtz determined further that 2.6 per cent. of the heat given off by the body represents the heat of the excrementitious matter; 2.6 per cent. is required to warm the air which we breathe; 14.7 per cent. passes away in the water liberated from the surface of the lungs; while 80.1 per cent. is either radiated from the surface of the body or required to evaporate the perspiration. When we remember that all of this work that Helmholtz did on animal heat was new work and accomplished with instruments which he devised for the occasion we are compelled to give him great credit for the important additions which he had made to our knowledge in this field.

The subject of *fermentation* was one of the first subjects to engage the attention of this young medical man. Various theories had been put forward as to the cause of fermentation. It was known to be associated in some way with the yeast plant, but just how, was the matter under discussion. Helmholtz performed an experiment which went far toward solving the question at issue. He inclosed some sterile grape juice in a pig's bladder and immersed this in a vat of fermenting grape juice. After the lapse of a number of days it was found that the grape juice within the bladder had undergone no fermentation. It was concluded from this that the cause of the fermentation could not operate through the animal membrane. Helmholtz believed that it was the living yeast cell that caused the fermentation and that the liquid within the bladder did not ferment because the yeast cells could not pass through the bladder. This experiment by Helmholtz started others to experiment, and it was soon found that a filter paper or a plug of cotton would also protect sterilized grape juice from fermentation. It thus appears that Helmholtz was the pioneer in a line of experimentation from which has developed the whole modern science of bacteriology.

While Helmholtz was still in Berlin, before he had been called to his first professorship in Koenigsberg, he took up the study of energy, and after a mathematical

treatment of the subject, he presented, in July, 1847, his epoch-making thesis on the "Conservation of Energy" (Ueber die Erhaltung der Kraft). The principal points in this thesis were: 1, that energy is indestructible; 2, that energy may be transformed, but is never lost or destroyed. For example, the latent chemical energy of fuel may be liberated in the furnace; the steam produced may set the parts of the engine into motion; thus the energy of motion is the transformation of the original energy, some of which has escaped, but none of which has been destroyed. These were new ideas to most of the physicists of one-half a century ago. The conservative Magnus declined to express an opinion regarding the thesis of Helmholtz; Jacobi alone recognized the truth of it. Many of the physicists said: "This has already been well known to us. What does this young medical man imagine when he thinks it necessary to explain so minutely all this to us?" Poggendorff refused to print Helmholtz's article in his "Annalen." Finally, however, Du Bois Reymond's publisher, Reimer, not only published it, but paid Helmholtz for the manuscript, a thing quite unusual in those days, as at present for technical papers. Like all great discoveries and newly-formulated laws, this one had been long since foreshadowed by Newton, by Descartes and by Leibnitz, while Joule of Manchester and Colding of Copenhagen had several years before made thorough and conclusive experimental demonstrations of the principle of conservation of energy. In confirmation of this, note the following quotation from Colding's address of 1843, published by the Royal Society of Copenhagen: "Force is imperishable and immortal, and, therefore, where and wherever force seems to vanish in the performance of mechanical work, the force then merely undergoes a transformation and reappears in the new form." In the case of each one of these men the discovery seemed to be original and independent of other investigators. To Helmholtz belongs not the priority of the principle, but the credit for first presenting it in clear and unmistakable terms which made possible its application to problems of mechanics, as well as to problems of physiology. Helmholtz stands to the law of the conservation of energy the same relation that Darwin stands to the law of organic evolution: In both cases the field had been occupied by advanced scholars, but no one had succeeded in catching the ear of the public until these men in turn presented their theses in terms translatable into the living and moving thoughts of the people. This is only a repetition of what has occurred repeatedly in history of the development of the sciences.

In 1849 Helmholtz was made professor of anatomy, physiology and pathology in the University of Königsberg. The first physiological work of note which he produced in Königsberg was to determine the *velocity of the nerve impulse*. He used, in these preliminary experiments, the gastrocnemius muscle and the sciatic nerve of the frog. He used an especially elaborated set of electrical appliances which were far more accurate than any which had been used before in this field of research. With the help of these appliances he found that the rate of propagation of the motor impulse is about 100 feet per second. His method of procedure was to stimulate the nerve near to the muscle in one case or two inches away in another case, and determine the difference in time of the responses in the two cases. This difference represents the time required to traverse the two inches of nerve. Incident to this investigation Helmholtz found that however near to the muscle the

nerve be stimulated a certain time will elapse before the muscle can respond. This period has been called the "latent period." Helmholtz followed this by the determination of the rate of the propagation of the sensory impulse. For this he used the human subject and a new set of appliances. By establishing the new idea, namely, the "reaction time," and determining the difference in reaction time between the thigh and toe he was able to compute the rate of propagation of the sensory impulse to be 160 to 300 feet per second. These methods of Helmholtz are practically the same as those used in the laboratories of physiological psychology for determining reaction time, time of discrimination, etc.

Helmholtz's interest in electro-physiology and animal electricity did not seem to be one that inspired him to seriously take up the problems in this field and pursue them to a finish. On different occasions something turned his attention briefly to this subject, and on each occasion he made invaluable contributions, but more particularly in the apparatus with which the problem could be solved. Helmholtz's knowledge of physics was an important element in his equipment for this work. One of his first contributions was his modification of the inductorium in such a manner as to equalize the effect of make and break shocks, while before his modification the break shock as produced by the Neef hammer was much the more irritating. He invented the pendulum myograph, the muscle lever or simple myograph, the moist chamber, and various electrical devices for controlling the strength and time of the stimulus. He contrived the non-polarizable electrodes and formulated the generally accepted theory regarding the muscle currents and the electromotive force of the muscle cell.

The next notable work which Helmholtz accomplished was the invention of the *ophthalmoscope*. His own words as to how he hit upon the idea may be of interest:

"I was endeavoring to explain to my pupils the emission of reflected light from the eye, a discovery made by Brücké, who would have invented the ophthalmoscope had he only asked himself how an optical image is formed by the light returning from the eye. In his research it was not necessary to ask it, but had he asked it, he was just the man to answer it as quickly as I did, and to invent the instrument. I turned the problem over and over to ascertain the simplest way in which I could demonstrate the phenomenon to my students. It was also a reminiscence of my days of medical study, that ophthalmologists had great trouble in dealing with certain cases of eye disease, then known as black cataract. The first model was constructed of pasteboard, lenses and cover glasses used in the microscopic work. It was at first so difficult to use, that I doubt if I should have persevered unless I had felt that it must succeed; but in eight days I had the great joy of being the first who saw before him a living human retina."

It was first described in the paper entitled, "Beschreibung eines Augenspiegels zur Untersuchung der Netzhaut im lebenden Auge." Though many changes have been made in the details of construction of this instrument the most modern and complete ophthalmoscope possesses no optical qualities not possessed by the one which Helmholtz first devised. The invention of this instrument opened a new era not only for ophthalmologists but also for practical medicine, as the retina may be regarded as an outlying portion of the brain. The examination of the fundus of the eye then gives to the physician information as to the pathological changes

occurring in the nerve centers. Thus it is of service in the diagnosis of inflammatory actions in the brain both acute and chronic; of changes in the meninges; in locomotor ataxia; of the various forms of Bright's disease and very many other maladies (McKendrick). In 1858, at the Ophthalmological Congress in Heidelberg, Helmholtz was presented with a cup, on which was inscribed the words, "To the creator of a new science; to the benefactor of mankind in thankful remembrance of the invention of the ophthalmoscope." Twenty-eight years later, at the same university, at a meeting of ophthalmologists, Helmholtz was presented with the von Graefe medal in recognition of the services which he had rendered to mankind in the invention of the ophthalmoscope. The presentation was made by Donder, who closed his presentation speech with the words: "May this gift still remain to you a gratifying symbol of the privilege you enjoy of living in a generation that honors you as its benefactor."

Helmholtz's interest in physiological optics began with his invention of the ophthalmoscope, but it did not end until he had completely mastered the whole field and written his classic work on the subject of physiological optics. The second problem which he attempted concerned the *optical constants of the eye*. In order to determine the curvature of the refractive surfaces Helmholtz devised the *ophthalmometer*. Without stopping to describe this instrument, it will be enough to give some of the results obtained with its use. Helmholtz found the radius of the curvature of the anterior surface of the cornea to be 7.829 mm., the radius of the curvature of the anterior surface of the lens 10 mm., and the radius of the posterior surface of the lens to be 6 mm., the distance of the posterior surface of the lens from the anterior surface of the cornea to be 7.2 mm. The distance of the anterior surface of the lens from the cornea is 3.6 mm. during rest and about 3.2 mm. during accommodation. From the above values Helmholtz calculated the index of refraction of the lens to be 1.4371 and that of cornea to be 1.3365. Helmholtz states of these optical experiments on the eye, that they fitted him especially for the solution of the problem that was engaging many of the physiologists and clinicians, namely, the problem of *accommodation*. Helmholtz's solution of the problem of accommodation, though antedated by that of Kraemer, was perfectly independent and was by far the most exhaustive study and most complete solution that had appeared up to that time.

The next subject to engage Helmholtz's attention was that of *color sensation*. Up to the time of Helmholtz, ideas of color had been based largely upon experiments with pigments. Helmholtz began to experiment with the spectral colors and found it necessary to reconstruct the whole theory regarding composite colors. He found: 1, that red, green and violet are the primary spectral colors; 2, that the quality of every luminous sensation depends on three variables: intensity, tone and degree of saturation; 3, that there are in the retina three kinds of nerve elements, each of which is especially responsive to the stimulus of color of one wave length and much less so to others. Thus when the three sensations are equally excited white light is the result; green is caused by a very weak violet stimulation, a stronger red and a still stronger green stimulation. At each end of the spectrum we have only the simple sensations of red and violet, and all the intermediate color sensations are compounds of varying proportions of the three primaries.

According to this theory, red blindness is attributable to the absence of red sensation, and green blindness to the absence of green sensation. As this represents Helmholtz's amplification and extension of Young's Theory it is known as the Young-Helmholtz Theory of Color Sensation.

We have briefly reviewed the more important contributions of Helmholtz to physiological optics. His experimental research on this subject was made mostly in Koenigsberg between the years of 1849 and 1856, but his great work, "Handbuch der Physiologischen Optik," was published in 1866, when he was in Heidelberg. This work is a classic and will be so considered through ages yet to come. "Everywhere one feels the grasp of a matter, whether in the exposition of the subject in hand or in its mathematical treatment" (McKendrick).

Next to his physiological optics, his greatest work was on *physiological acoustics*, for the most part accomplished during his professorship at Bonn (1856 to 1859), though some portions of it were done at Koenigsberg. The result of all of this work in acoustics was summed up in his masterpiece entitled, "Die Lehre von den Tonempfindungen als Grundlage für die Theorie der Musik" (Sensations of Tone as the Physiological Basis of Music). Published in Heidelberg, 1863.

Though his work on hearing has been less productive of ideas applicable in clinical medicine, it is no less profound and exhaustive, and will, like the other, remain among the classics in physics, in physiology and in psychology. The title of the work suggests that the master was addressing his presentation of the subject of physiological acoustics to the musicians. Curiously enough, it has been far less used by them than by workers in the several other fields mentioned. The reason is not far to seek: The masters in music no less than their pupils give their attention almost wholly to the esthetic side of their art. They are willing to accept without mathematical, anatomical or experimental proof certain fundamental principles of harmony, and in the elaboration of their art to be guided by these accepted principles and by any intuitions or inspirations which might come to them as natural gifts.

In his work on physiological acoustics, as in that in physiological optics, Helmholtz began his researches with a minute study of the anatomy of the organ in question; this was followed by a searching inquiry, both experimental and mathematical, into the physical properties and relations of the mode of motion (sound, light) concerned. Thus equipped he could hardly miss making notable contributions to the subjects.

Later subjects of study by Helmholtz were: 1. The cause and quality of the human voice. 2. The mechanics of respiration. 3. The movements of the eyes in binocular vision. 4. The visual horopter. These later studies, together with the publication of his works on acoustics and optics, occupied him during his professorship in Heidelberg (1859 to 1871).

Helmholtz was called to the professorship of physics in Berlin in 1871. For twenty-three years he occupied in Germany a position similar to that which his friend, Sir William Thompson—Lord Kelvin—occupied in England.

It is doubtful if the world has ever produced a man who combined greater breadth of knowledge and greater depth of wisdom, with keenness of vision, persistency and patience of pursuit, and modesty of claim. The debt of physiology to Helmholtz is inestimable.

## PSYCHOLOGY.

The psychology of 1850 was the fruit of the introspective method of research. The value of this method as applied in the study of the higher intellectual processes can not be gainsaid. Even here, however, it is to be recognized as only one of several methods of extending knowledge of the higher intellectual faculties and processes.

The psychology of to-day is an experimental science, or, if not wholly so, at least the foundations and a large part of the superstructure represent experimental and laboratory research, the introspective method coming in only at the last to complete and round out the superstructure.

The metamorphosis in the methods of research in psychology has had the effect of giving it a new and much higher standing in the scientific world than it ever had in the period of a purely introspective method.

This renaissance of psychology is due in very large measure to the influence of von Helmholtz. A curious feature of the relation of Helmholtz to psychology is that those contributions of his which have come to be fundamental in psychology were at the time they were made published as contributions to physiology. In this connection it is significant to remember that the methods which Helmholtz originated in the fifth and sixth decades for the study of the senses and sensation, are the methods of the new psychology of the last three decades of the nineteenth century.

The contributions of Helmholtz to this realm of human knowledge are more notable in their character and quality than in their number and quantity. They mark Helmholtz in his relation to psychology as a pioneer and a pathfinder rather than a developer and finisher. This last is characteristic of his work in psychology alone. In physiology and physics the world has never produced a man who went deeper for the foundations of his subjects and who at the same time developed them more extensively and finished them more completely. His work in physiology and physics is at the same time the inspiration and despair of the leading students in these fields. That his relation to psychology was that of an explorer only may be readily accounted for in the fact that at the time he was working upon problems of sensation and the senses, psychology was the product of the introspective method alone, and the relation of his laboratory methods to the armchair meditations of the mental philosophers and metaphysicians was not at once apparent, and a considerable period elapsed before the psychologists began to apply the methods of Helmholtz to their branch. When they did they found his work an inspiration and a guide without finding the subjects so completed that there remained little to do. In the hands of such men as Wundt, Ladd, Stanley Hall, Cattell, König, Münsterberg, Ziehen, Baldwin and Scripture, all inspired by the pioneer work of Helmholtz, the new psychology has been put upon a thoroughly experimental basis.

Let us now consider briefly those studies of Helmholtz which may be accepted as making the basis of the new psychology.

In 1850, when Helmholtz was determining the velocity of the nerve impulse in sensory nerves, he originated the idea of the *reaction time*. The way in which this was applied is described under the head of Physiology. We know of what fundamental importance and far-reaching application this idea of the reaction time has

been in psychology. Growing out of this idea we have the *discrimination period* and the *judgment period* or *decision period*.

Early in the fifth decade Helmholtz began his series of studies on the Sensations of Tone or the sense of hearing. As a part of this series of researches he made an exhaustive study of the anatomy of the tympanum and labyrinth. That portion of his work which was directed toward the nerve endings and the specialized epithelium of the labyrinth covers ground now included in psychology. Helmholtz worked out the only tenable theory as to the way in which these end organs of hearing are stimulated by the mechanical vibrations which beat upon the membrana tympani as sound waves. He went farther, and discussed the mechanism of cerebral sensation and the physiology (or psychology) of the sense of harmony in musical tones. In fact, Helmholtz's great work entitled "Sensations of Tone as a Physiological Basis of Music" is a classic for the psychologist as well as for the physicist and the physiologist.

We need to make only brief mention of the work of Helmholtz on the sense of vision. It was as exhaustive as that on hearing and was of as great importance to psychologists. Particularly important are the studies of the retina and its neuro-epithelium (rods and cones) and its nerve cells with the part that these play in visual sensation. Helmholtz studied especially the color sense. He revived and extended Young's theory of color sense; and this new theory has since been known as the Young-Helmholtz theory.

The new psychology had its birth in the studies of Wundt, begun in 1858 and leading to his "Beiträge zur Theorie der Sinneswahrnehmung," and later to his notable work on "Physiologische Psychologie," published at Heidelberg, in 1874.

Up to the present time the psychologists have not seemed to accord to Helmholtz the credit due him for the initial impulses which he undoubtedly gave to their department of physiology. Perhaps the physiologist tends to overestimate the importance of the work of their confrère Helmholtz; but it seems impossible that work such as his, lying on the border line of pure psychology and quite within the field of physiological psychology, should not have exerted a profound and far-reaching influence on all subsequent work in psychology.

## THE DEBT OF OTOTOLOGY TO HELMHOLTZ.

B. ALEX. RANDALL, M.A., M.D.

PHILADELPHIA.

The influence of Helmholtz upon otology is almost incalculable, although signalized by no instrument like the ophthalmoscope with its epoch-making application and its huge clinical field. Reflectors of various kinds to illuminate the aural, nasal and pharyngeal cavities had been somewhat used before his day and received but moderate impulse directly through his ophthalmoscope, for it was really the perforated concave mirror of Hoffmann and Ruetz which became the aurist's illuminator; but they did lead to marked gain in diagnosis and treatment through rivalry with the ophthalmic progress which he had inaugurated. His advance lay principally in his contribution to the underlying science of acoustics. This he found in almost the rudimentary and empirical phase known to Pythagoras; and just as his disproof of spontaneous generation made a beginning of minute biological study, and his physical corollary of the conservation of energy became the basis of all modern material science, so he here applied

the fundamental principles and proceeded by experiment and deduction to build up a rounded science of acoustics. He filled out the many gaps in the observation of phenomena until the bulk of the observations were really his own, and then linking these with all otherwise discovered, he made them the coherent parts of general laws. So complete was his study that he could not only explain the known facts and point out the lines of new discovery, but could also define the probable limitations to practical advance in the dependent arts.

Physiologist, as well as physicist, he did not stop at the external phenomena, but worked out the transmission of sound through the aural apparatus to the end organ in the labyrinth, himself supplementing the anatomical details of the most advanced investigations; and while his conclusions have been combated, and alternative views have been plausibly presented, the Helmholtz theory still receives predominant acceptance. Nothing more strongly demonstrates the skill of Helmholtz, the teacher, than the matter-of-course acceptance as fundamental of most of his discoveries and the fact that his classical treatises have remained the text-books of the world. Yet the lucidity of the language has made translation almost wholly needless and his desire to simplify the mathematical elements of the problems, has put them in form which tempts many a reluctant student to deeper study than any other contributor to the subject has been able to inspire. Keenly alive to the artistic side of music, he has cleared much with regard to its composition and the musicians in their narrower field of esthetic production are largely indebted to him for his explications, and the physiology of such impressions has been developed to what seems nearly its full limit.

It is only indirectly, then, that we, as practicing otologists, owe to von Helmholtz our present means of diagnosis upon which, of course, must hang treatment as well as comprehension. Having defined the end organ of hearing and so differentiated the percipient from the conducting apparatus, he banished the term "nerve deafness" from the position of a broad category cloaking much ignorance and restricted it to a properly narrow group of our cases. He made the tuning-forks and other tone-producing apparatus the practical instruments in medical hands which they now are. He made clear the function and mechanism of the drumhead and ossicles in a way that forbids any undue regard for them as essential to useful hearing or an equally unscientific indifference which would needlessly remove them as unimportant. Many aurists do not recognize their debt to von Helmholtz and shortsightedly preach or practice in contravention of the principles which he has discovered or formulated; but the inevitable result is a fall in ruin of any structures they may have fondly reared and their own heads have often suffered in the collapse. His treatises will never make light reading for beginners, but the ophthalmologist and otologist who hopes to take and hold rank among his colleagues must always count as essential to his education a close study of the writings of Herman von Helmholtz.

**Anal Fissure Simulating Coxalgia in Children.**—The subjective symptoms in the case of three children observed by Svebla seemed to indicate hip-joint disease, but the discovery of a fissure in the anus revealed the true character. After the cure of the fissure the pains in walking, the limping and the deformed attitude, all vanished.—*Vratch*, December 29, 1901.

## CONTRIBUTIONS OF HELMHOLTZ TO PHYSICAL SCIENCE,

ESPECIALLY WITH REFERENCE TO PHYSIOLOGICAL OPTICS, INCLUDING THE DYNAMICS OF EYEBALL MOVEMENTS AND OF ACCOMMODATION.

ARTHUR W. GOODSPEED, PH.D.

PROFESSOR OF PHYSICS IN THE UNIVERSITY OF PENNSYLVANIA. PHILADELPHIA.

Helmholtz's attention was directed to the subjects to be discussed in this paper while very young. Even while attending the gymnasium and reading Cicero and Virgil, for which he had little taste, Helmholtz was pondering on various problems in optics not met with in text-books, and which served as a basis some years later for the construction of the ophthalmoscope. The mathematics of physical problems always came easy to him, not that he seems to have had any special love for pure mathematics for its own sake, but only as a means of solving the questions which interested him. His mathematical ability was of a very high order, and this fact seems all the more remarkable when it is noted that he never had any systematic training in this branch of science, as have most other eminent mathematical physicists. His knowledge in the more advanced departments of mathematics was acquired entirely through his own unaided efforts. Although circumstances of his early life made it best that he be educated for the medical profession, his taste was always on the side of pure science. Evidence of this is given by his own words, found in a lecture on "Thought in Medicine," delivered in 1877: "My own original inclination was towards physics; external circumstances obliged me to commence the study of medicine."<sup>1</sup>

Helmholtz appreciated, however, the great advantage to be gained by a thorough course of medical study, and in after years never regretted the time he had been obliged to spend on this and allied subjects.

Without detracting at all from the fame of Helmholtz, it must be noted that the state of physical science in Germany at the time he began his career was just right for a boom. Physiology was not admitted to be based on physics and chemistry, and, therefore, experiment and observation were not resorted to, to any extent, for the solutions of physiological problems. This was the case doubtless because it was profoundly believed that a mysterious vital force was responsible for most physiological changes.

France, and especially Paris, on the other hand, during this dormant period in Germany, had been leading in investigation, especially along physical and chemical lines. This condition soon had a decided influence upon Germany through the association of young men educated in Paris and holding positions subsequently in their home universities. From this beginning, then, the objective science school became prominent as opposed to the metaphysical school. To the former belonged Brücke, Du Bois Reymond and Helmholtz, who founded with others the Physical Society of Berlin. Of this group, according to Wiedemann, Helmholtz was the most distinguished, and certainly his superb work in later life in nearly all of the departments of science represented by the founders of the Physical Society quite justify Wiedemann's first impressions of him.

Helmholtz's aptness for both mathematics and physics led him to look upon physiology as attractive in furnishing an abundance of problems suitable for investigation along the physical and mathematical lines, rather than

on its own account. The physics of the eye, as well as of the ear, present notable examples of this sort, and both these organs were critically investigated by Helmholtz and a vast amount of most valuable and accurate information obtained. Also Helmholtz's investigations on the phenomena of animal heat led him gradually to lay the foundation for the great conservation principle as applied to energy as a whole.

His remarkable paper, "Ueber die Erhaltung der Kraft" was written when he was only 25 years old. Fifteen years later, in 1862, he had to force the idea embodied in his original essay upon the scientific world against much opposition, even Poggendorff refusing to publish his paper in the *Annalen*. The work was, however, published otherwise and its value very soon recognized. Of course the fundamental idea dates back perhaps to Newton, but it was never generally recognized or half understood.

#### PHYSICAL AND PHYSIOLOGICAL OPTICS.

One of the most important as well as practical departments of Helmholtz's researches was that of physical and physiological optics, and we shall now examine a few of the various problems therein involved, most of which he studied to conclusions the truth of which have never been questioned.

It is the general impression among people that the human eye, when considered in its normal type, must be about as perfect an optical instrument as can be imagined. Helmholtz was among those to point out, however, what is now well understood, viz., that the eye is so far from perfect that he remarked in his "Physiological Optics": "Should an optician send me an instrument having like optical defects, I should feel justified in sending it back." He further remarks, however, that "the defects which may be traced in the eye, *considered as an optical instrument*, do not detract from the excellence of the eye *considered as the organ of vision*." Physical perfection is quite a different thing from practical perfection considered from the point of view of a physiologist. The latter had persisted in failing to recognize the physical defects, though we find "that Newton pointed out the chromatic aberration of the eye two centuries ago; that D'Alembert, in 1767, proved that the lenses of the eye might have as great a dispersive power as glass without the want of achromatism necessarily becoming noticeable; that the celebrated optician Dolland, the inventor of the achromatic lens, showed that the refractions which take place in the eye all tend to bring the violet rays towards the axis more than the red; that Maskelyne the astronomer, Wollaston the physicist, Fraunhofer the optician, and other scarcely less distinguished men of science have made actual measurements of the distances of the foci in the human eye for the different rays of the spectrum. The persistence with which writer after writer has asserted the achromatism of the human eye appears so extraordinary that it can only be accounted for by the prevalence of the preconceived notion that the eye is absolutely perfect—a notion not without its reason and grounds in the fact of the exquisite adaptation of the organ of sight to the needs of humanity."<sup>2</sup>

Although a method of examining the retina had long been desired and almost had been found before Helmholtz, it remained for him to devise finally the instrument in its completeness, viz., the ophthalmoscope. Although many of these instruments have been made since, none of them present essentially any new methods

for illuminating and examining the retina. It was in 1851 that Helmholtz first described the ophthalmoscope, and during the last fifty years this little instrument has been probably the chief means of extending the knowledge of oculists regarding the diseased and healthy conditions of the eye. In this way the substance of the lens and the state of the fluids can be directly examined, the causes of impaired vision can be discovered, and the nature of many maladies made out with reasonable certainty. Many insidious troubles can thus be detected and very likely successfully treated and cured before the organ has become permanently diseased. In some cases even, as is well known at the present time, the ophthalmoscope gives the most certain evidences of the existence of obscure and often unsuspected diseases of other parts of the body. In 1858, at a meeting of the Congress of Ophthalmologists at Heidelberg, Helmholtz was presented by von Graefe with a cup inscribed, "To the creator of a new science, to the benefactor of mankind, in thankful remembrance of the invention of the ophthalmoscope." Some years later the von Graefe medal was instituted with which to honor, once in ten years, the man, without regard to nation, who should have done most for the science of ophthalmology. The first medal of this foundation was presented to Helmholtz in August, 1886, at the occasion of the celebration of the 500th anniversary of the founding of the University of Heidelberg.

The details of the ophthalmoscope differ somewhat with different makes, but the general principles are familiar to all medical men and to most physicists. The instrument consists essentially of a converging or concave mirror for concentrating the light of a lamp, conveniently placed for the purpose, through the pupil to illuminate the retina or other parts of the eye to be examined. The eye of the observer is behind a small hole in the center of the mirror. In front of this opening and therefore between it and the part under examination is a magnifying lens or combination. The whole arrangement is very simple, efficient and easy of manipulation.

Another instrument invented by Helmholtz, by means of which the optical constants of the eye can be measured accurately, is the ophthalmometer. Such a piece of apparatus must necessarily be more complicated than a simple observing device and requires far more skill to operate it for accurate results. It is fully described and the method of using it discussed in Chapman's "Human Physiology." In the hands of this author a few years ago the average radius of curvature of the normal cornea in fifty cases measured was found to be 7.797 millimeters in the vertical plane and 7.552 millimeters in the horizontal plane.<sup>3</sup>

Helmholtz made use of the ophthalmometer also in the solution of the problem of accommodation of focus for different distances. An ordinary optical lens, as, for example, a camera combination, has a definite focal length, i. e., a fixed distance at which a beam of parallel rays incident on one side will be brought together on the other side. Suppose a camera adjusted with its ground glass showing sharply defined the image of a very distant object. Direct the camera to an object near at hand and the image will be out of focus. Theoretically sharp definition may be restored in two ways—either by moving back from the lens the ground glass a small distance, or by changing the curvature of the lens surfaces. The latter, of course, is impracticable,

2. Discoveries and Inventions of the Nineteenth Century, p. 343.

3. Proceedings Academy Nat. Sciences, 1893, p. 349.

and the readjustment of distance from plate to lens is easily accomplished. Now, the eye is a small camera and we easily and rapidly adjust for the distinct vision of both near and far off objects. But how is this done in the case of the eye? Do we change the position of the retina relative to that of the lens and cornea, or do we change the shape of the lens? This problem Helmholtz attacked and studied very satisfactorily by means of the ophthalmometer. He was ignorant at the time that it had been shown already by Cramer that in changing the eye adjustment suitable for far objects to one suitable for near ones the convexity of the lens increases. The three images observed by light reflected from the eye, one formed by the anterior surface of the cornea and one each by the two lens surfaces had been progressively discovered some years before, but nobody before Cramer had noticed that in changing the eye adjustment as above, the middle image moved nearer the outer one and at the same time became smaller. As this image is a virtual one formed by the anterior surface of the lens, both changes indicate an increase in curvature of this surface.

To perform this experiment more conveniently than can be done in a dark room Helmholtz invented an instrument he called a phakoscope. It is simply a shallow triangular black box truncated at the corners, with openings through the corner faces and in one long side. The eye to be examined is placed at the corner opposite the side opening and looking through or at the same. At one of the other corners is the observer's eye and at the third is the light. The method is obvious.

The ophthalmometer was now used to measure the sizes accurately of the three images under various sets of conditions. The essential parts of the instrument consist of a pair of plano-parallel glass plates about 2 centimeters square and 6 or 8 millimeters thick, whose refractive index has been measured with the greatest accuracy and also their thickness; a short focus telescope and a rod or frame for holding the luminous object, images of which are to be formed by the eye surfaces under examination. The plates are mounted one above the other initially co-planar and independently capable of rotation about the same vertical axis. This combination can be rotated at will, the plates in the same or opposite directions and the angle determined with great precision on a suitably graduated circle. It is placed on the optical axis of the telescope, the eye to be observed being located on the same axis looking into the telescope and beyond the plates. The source of light is near the observer's eye and images of it can be seen through the telescope formed by the surfaces of the eye to be examined. It is a well-known fact that if an object be viewed obliquely through a plano-parallel plate it will seem laterally displaced in amount depending on the angle and on the thickness of the plate, as well as upon its index of refraction. This is the principle of the ophthalmometer. If the two plates be rotated in opposite directions the image will divide, half moving to the right and half to the left. If the rotation be continued until the displacement is equal to the width of the image, this value can be calculated from a simple formula involving the rotation angle which is observed and the constants of the instrument previously determined. By this arrangement Helmholtz proved that the shape of the cornea does not change, but that the anterior surface of the crystalline lens changes its radius from 10 millimeters to 6 millimeters in viewing a near object after looking at a remote one; that the radius of the posterior surface changes from 6 to 5.5 millimeters

only. Also that the minimum distance from the cornea to the anterior lens surface is 3.3 millimeters, while the maximum distance is 3.7 millimeters; that the minimum thickness of the lens is 3.8 millimeters; maximum thickness 4.3 millimeters. These values, when considered together with the indices of refraction of the several media concerned, easily account for the changes of focal length required for accommodation. Helmholtz made this investigation quite complete by offering an explanation of the mechanism of accommodation which is now universally accepted as the true one. The matter had been studied before by Thomas Young, C. Weber, Cramer, Donders, Brücke, and others, so that the anatomy was well understood. In the words of McKendrick,<sup>4</sup> Helmholtz's conclusion was, "that in accommodation the fibers of the ciliary muscle contract and tend to draw the ciliary processes of the choroid forward. Passing in close proximity to these processes, and connected with them, is a thin transparent membrane, the hyaloid membrane, which lines the posterior chamber of the eye. Anteriorly this membrane divides into two layers, one passing before and the other behind the lens, forming what is termed its capsule. The lens is thus bound down, as it were, by its capsule, more especially by the portion of it passing over its anterior surface. When therefore the ciliary processes are pulled forward by the ciliary muscle, the tension of the layer of the capsule in front of the lens is diminished, and the anterior surface of the lens bulges forward by its elasticity. There are certain muscular fibers of the ciliary muscle that also assist in this beautiful mechanism. When the eye is again directed to a distant object, the fibers of the ciliary muscle relax, and the lens is flattened by the pressure of the capsule." Helmholtz further proved that the conditions above explained are not only the *necessary* ones, but that they are also *sufficient* for the accomplishment of accommodation.

This investigation, with its results, is deemed by McKendrick "one of the greatest triumphs of modern physiology."

#### COLOR SENSATIONS.

During the period of 1852 to 1856 Helmholtz devoted much time to color, more especially to the subjective side of it, viz., color sensation. Assuming the wave theory of light, as some years before demonstrated by the great work of both Thomas Young and of Fresnel, Helmholtz directed his attention to the mechanism of color sensation. Young had concluded that there are three simple color sensations, viz., red, green and violet, since each of these color sensations can be produced only by objective waves of a limited range of length which can be definitely measured physically, and since all the other colors may be matched by a judicious mixing of these three. The quality of the resultant hue depends on the proportional intensity of each component in the mixture and the total brightness is the sum of the component intensities. Brewster developed the red, yellow and blue primary color theory, which led to much controversy and has failed to meet the requirements. Many of Brewster's experiments were made with pigments instead of with colored light. Helmholtz stepped in at this stage and invented a simple method of superposing any part of one spectrum on any part of another, thus to study the result of the numerous combinations possible. By varying the relative intensities of the two spectra he could at will change the relative brightness of the colors to be mixed.

4. Hermann von Helmholtz, by Dr. T. G. McKendrick, p. 102.

This method is more exact than Maxwell's, in which the eye is made to receive consecutively various color stimuli, and which relies on the persistence of vision for the resulting sensation. By Helmholtz's method the retina receives at the same time, in the same place, the two or more stimuli applied. By mixing the spectral colored lights in pairs he was able to reproduce all the spectrum colors except red, green and violet, and also to produce many shades besides, the names of which at the present time largely depend on convention. He further concluded that a definite color sensation required for its complete definition the determination of three values, those of hue, of saturation and of luminosity. The first depends on the objective wave length of the color present; the second on the ratio of the quantity of the pure color to the quantity of white present; the third affects the intensity of the sensation and is partly

extended it to account for various phenomena not studied by Young. This general theory, known as the Young-Helmholtz theory of color sensation, accounts for most of the facts in a very satisfactory manner. It serves remarkably well in accounting for color blindness of various kinds; also for contrast effects; subjective color (due to retinal fatigue), etc.

Many physiologists and modern psychologists, especially the latter, do not accept this theory as the correct one, but are inclined to the Hering<sup>5</sup> theory, which supposes actual change in a visual substance, some of the processes being of a "constructive-assimilating kind" and others of a "destructive assimilating kind," but the scope of this paper does not permit a discussion of the relative merits of these two theories. Although there are some cases from the point of view of a psychologist not explicable on the Young-Helmholtz

dependent on the actual amount of radiant energy incident on the retina. Near the end of his life Helmholtz held that this third characteristic, viz., luminosity, really plays a more important part in the theory of color perception than was formerly supposed. By exceedingly careful analysis of white light, assisted by Arthur König, he specified definitely three fundamental color sensations, a nearly pure carmine red, green, and ultramarine blue. This in the main, it will be remembered, was the classification advanced by Thomas Young in 1802, whose basic assumption was, though not so clearly stated as by Helmholtz, that the optic nerve terminates on the retina in three distinct sorts of organs which, when stimulated, give rise to the sensations of red, green and blue respectively. According to this theory, the particular set to be stimulated depends on the wave length of the incident light. Helmholtz accepted this theory in general as correct and by his careful studies

hypothesis, it certainly appeals very strongly to physiologists and was firmly adhered to by Helmholtz and his associates to the time of his death, only seven years ago.

#### OCULAR MOVEMENTS.

Another special study taken up by Helmholtz appropriate for consideration in this paper was that of the mechanics of the eye movements. It does not seem at first as if this subject should require a very great amount of study for the solution of the problems presented; but in the language of McKendrick in his life of Helmholtz, "only those, however, who have read the chapters on the subject in his 'Physiological Optics' can form a conception of the amount of work expended upon it. The bibliography alone is a model of literary research." Helmholtz's work in this department of optics was done from 1862 to 1867, although he wrote two or three

5. Wien. Sitzbericht. lxxvi, lxxviii, lxxix, lxxx. 1872.

more papers ten or fifteen years later. In 1862 appeared a preliminary paper which investigated the surface, images of any point of which would fall on homologous points on the two retinas, thus giving rise to the sensation of a single image. Such a surface had been called the horopter by Aguilonius in 1613, and it was shown by Helmholtz that when viewing the horizon the horopter is a horizontal plane passing through the feet. In general the case is not so simple.

In 1863 he published two mathematical articles on eye movements illustrated by clever experiments. In 1865 appeared three contributions on phases of the same subject. In 1864 he gave before the Royal Society a famous paper "On the Normal Motions of the Human Eye in Relation to Binocular Vision." Also two papers on the horopter were published in the same year.

At the International Ophthalmological Congress at Paris in 1867 Helmholtz read a paper on "Stereoscopic Vision." The anatomy of the subject would be out of place here, but the voluntary and involuntary muscle

to a single object; and further, that the problem can not be solved from a purely anatomical study.

#### APPENDIX—DESCRIPTIVE LIST OF THE OPHTHALMOSCOPES

IN THE HISTORICAL EXHIBIT, ST. PAUL MEETING OF THE AMERICAN MEDICAL ASSOCIATION. PREPARED BY DR. HARRY FRIEDENWALD, BALTIMORE.

##### Older Ophthalmoscopes.

HELMHOLTZ. 1851.

1. Original form, described in Helmholtz's monograph "Beschreibung eines Augenspiegels, etc., Berlin, 1851." Formerly in the possession of Albrecht von Graefe. See Plate I, No. 1. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

2. Similar. Angle of glass plates 25°. Formerly belonged to Dr. Julian J. Chisholm. Loaned by Drs. Herbert Harlan and F. M. Chisholm, Baltimore, Md. See Plate I, Fig. 12.

3. Similar to 1. Angle of glass plates 30°. Presented in 1853 by Dr. Eduard Jaeger, of Vienna, to Dr. John Brinton, and in 1870 by the latter to Dr. Wm. Thomson, of Philadelphia. See Plate I, Fig. 49. Loaned by Dr. Thomson, through Messrs. Bon-schur & Holmes, Philadelphia.

4. Modification. The lenses are inserted in a slit at the side. See Plate I, Fig. 41. Sent to Dr. John H. Dix, of Boston, by Prof. Sichel, of Paris. Loaned through kindness of Dr. B. Joy Jeffries, Boston.

actions were carefully differentiated by Helmholtz, and he demonstrated by the higher mathematics the truth of the so-called "Listing's Law," which provides for all the degrees of freedom of rotary motion for the eyeball except a pure rotation about an antero-posterior axis through the optic center of the lens, i. e., about the optic axis. Within a few years a paper on this subject by Carl Weiland<sup>6</sup> throws some doubt on the generally accepted views of eyeball movements as developed by Listing and Helmholtz.

While studying the general case of the horopter Helmholtz invented the telestereoscope which, in the hands of a well-known German firm, has taken the size of an ordinary binocular opera glass and shows distant objects in relief as if the two eyes subtended the same angle that they would subtend if moved much nearer.

Helmholtz concluded from his final researches on binocular vision that the homologous positions on the two retinas of the images of an object do not entirely explain the mental interpretation of these as belonging

5. Similar to 4. Made in Halle, Germany. Loaned by Dr. H. B. Young, Burlington, Ohio.

RUETE. 1852.

First concave mirror. First practical instrument for indirect method. Described in "Der Augenspiegel und das Optometer. Göttingen, 1852." See Plate II. Loaned by Dr. Haskett Derby, Boston.

COCCIUS.

"See Anwendung des Augenspiegels. Leipzig, 1853."

1. Plane mirror with condensing lens attached. Plate with circular perforation to reduce size of mirror. See plate III, Fig. 71. Loaned by Dr. Lucian Howe, Buffalo.

2. Modification: Circular mirror. Plane, metallic mirror, with convex lens attached, distance between mirror and lens adjustable. See Plate III, Fig. 26. Makers: Messrs. Tiemann & Co., New York. Loaned by them.

3. This instrument has a fixed distance between the ophthalmoscope and the lens; in the original instrument this distance is variable. See Plate III, Fig. 25. Loaned by Messrs. Tiemann & Co., New York.

4. With slide containing six lenses behind mirror. Loaned by Wills Eye Hospital, through Dr. Conrad Berens, of Philadelphia.

ZEHENDER. 1854.

1. Original form (described in Graefe's Archiv, I, 1, 121). Convex, metallic mirror. See Plate III, Fig. 47. Loaned by Dr. F. Koeller, of Pittsburg.

2. Slightly modified. Makers: Messrs. Otto and Reinders, New York. See Plate III, Fig. 29. Loaned by Dr. Haskett Derby, of Boston.

BURROW. 1856.

1. (See Graefe's Archiv III, 2, 68.) Heterocentric Reflector: Made of biconvex lens silvered on back, in pillbox case. Loaned by Dr. B. Joy Jeffries, of Boston.

<sup>6</sup> Archives of Ophthalmology, vol. xxvii, 1898.

2. Similar to 1, but with handle attached. See Plate III, Fig. 30. Loaned by Dr. Haskett Derby, of Boston.  
 3. Modification by Elsberg, revolving sector with four lenses back of mirror. See Plate III, Fig. 20. Loaned by Messrs. Tiemann & Co., New York.

JAEGER. 1854.

1. Large Jaeger (described in "Staar and Staar Operationen. Wien, 1854). Three reflectors: (a) plates of glass; (b) concave silvered mirror; (c) plane silvered mirror. See Plate III, Fig. 40. Used by Dr. Jeffries in Vienna in 1858 and 1859. Loaned by Dr. B. Joy Jeffries, of Boston.  
 2. Loaned by Dr. Haskett Derby, of Boston.  
 3. Loaned by Dr. Risley, of Philadelphia, through Messrs. Bonschur and Holmes, of Philadelphia.  
 4. The plates of glass are protected on the back by a metal shield with central opening. Loaned by Wills Eye Hospital, through Dr. Conrad Berens, Philadelphia.  
 5. Loaned by Dr. Barch, of St. Louis.  
 6. Mauthner's pattern. See Mauthner "Ophthalmoscopy," 1868, page 108; more compact than original. Formerly belonged to Dr. Noyes, of New York. Loaned by Dr. D. W. Hunter, of New York.  
 7. Similar to 6. Loaned by Dr. Wm. Thomson, of Philadelphia, through Messrs. Bonschur and Holmes, of Philadelphia.  
 8. Similar to 1. Loaned by Dr. C. H. Williams, of Boston.  
 9. Similar to 4. Loaned by Dr. C. H. Williams, of Boston.  
 10. Incomplete. Loaned by Dr. Callan, of New York, through Mr. E. B. Meyrowitz.

### Demonstration Ophthalmoscopes.

1. *Schweiggyer*: Demonstration Ophthalmoscope for two observers. Described in Berl. Klin. Wochenschr., 1871, p. 581. See Plate IV. (Similar to Sichel's instrument, as described in Graefe & Saemisch's Handbook, First Ed., Vol. III, p. 161.) Makers: Messrs. Paetz & Flohr, of Berlin; formerly in possession of Dr. Noyes. Loaned by Dr. D. W. Hunter, of New York.  
 2. *Graefe-Peppmüller*: Demonstration Ophthalmoscope. See Plate IV, Fig. 66. Described at the 50th Versammlung Deutscher Aerzte und Naturforscher, 1871. Loaned by Dr. Charles H. May, of New York.  
 3. *Graefe-Peppmüller*: Small mirror attached to Liebreich's Ophthalmoscope, similar to 2. Loaned by Dr. Harry Friedenwald, of Baltimore, Md.  
 4. *Schoeter*: Demonstration Ophthalmoscope: Small mirror set at angle just behind opening of Ophthalmoscope; described in Schoeter's Jahresbericht der Klinik fuer 1876, p. 51. Loaned by Dr. C. H. Williams, of Boston.

### Simple Ophthalmoscopes.

1. *Small Jaeger*: See Mauthner's "Ophthalmoscopy," p. 108, similar to early "Liebreich." Concave metal mirror. The fork holding the correcting lens is detachable. Makers: Messrs. Tiemann & Co., of New York. Loaned by them.  
 2. *Liebreich*: Earliest pattern. Metal mirror. Makers: Messrs. Paetz & Flohr, of Berlin. Loaned by Dr. W. B. Hunter, of New York (formerly in possession of the late Dr. Noyes).

11. *Dr. G. Strawbridge's Modification*. Three revolving Rekoss discs. See Plate III, Fig. 52. See Trans. Amer. Ophth. Soc., 1871, page 120. Loaned by Dr. Strawbridge, of Philadelphia, through Messrs. Bonschur and Holmes.

### Stationary Ophthalmoscopes.

LIEBREICH.

1. See Plate IV (described in Arch. f. Ophth., 1854, Vol. I, 2). Loaned by Dr. Hermon Thomas, of Philadelphia, through Messrs. Bonschur and Holmes, of Philadelphia.  
 2. Similar to 1. Loaned by Drs. Chisolm and Harlan, of Baltimore.  
 3. *Fixed Model of Vollin*: Made by Nachet, of Paris. See Plate IV. Loaned by Dr. Haskett Derby, of Boston.  
 4. *Galezowski*: 1862. See Acad. de Med. France, 7 Jan., 1862. This is a modification of Liebreich's Stationary Ophthalmoscope and of Hasner's. See Plate IV. Makers: Messrs. Otto and Reynard, of New York; formerly in possession of Dr. E. N. Brush. Presented to and loaned by Dr. Harry Friedenwald, of Baltimore, Md.  
 5. *Galezowski*: Concave metallic mirror and collecting lens contained in telescopic tube; opening on side for entrance of light; one end fits on patient's face; may be used in light room. Maker: Charriere, of Paris. Loaned by Drs. Herbert Harlan and Frank M. Chisolm, of Baltimore, Md.  
 6. *Galezowski*: Similar to 4 and 5, metal mirror. Loaned by Wills Eye Hospital, through Dr. Conrad Berens.  
 7. *Galezowski*: Similar to 4 and 5. Loaned by Dr. Charles H. May, of New York.

3. *Liebreich*: Earliest form, concave metal mirror. Loaned by Dr. B. Joy Jeffries, Boston.  
 4. *Liebreich*: Later model, concave metal mirror. Loaned by Dr. F. M. Chisolm, Baltimore, Md.  
 5. *Liebreich*: More modern form, glass mirror, long handle. Loaned by Messrs. Tiemann & Co., New York.  
 6. *Liebreich*: Later model. Loaned by Dr. B. Joy Jeffries, Boston.  
 7. *Liebreich*: Small model. Loaned by Messrs. Tiemann & Co., New York.  
 8. *Liebreich*: Very small form. Loaned by Dr. C. H. Williams, Boston.  
 9. *Anagnostakis*: Similar to Liebreich, but of very short focus. Described in "Essai sur l'exploration de la Retine." Paris, 1854. Made by Soleil, Paris. Loaned by Dr. C. H. Williams, Boston.  
 10. *Anagnostakis*: Similar to 9. Loaned by Wills Eye Hospital, through Dr. Conrad Berens, of Philadelphia.  
 11. *Nachet*: Modification of Liebreich: Small revolving disc with four correcting lenses attached to back of mirror. Loaned by Dr. Flemming Carrow, Ann Arbor, Mich.  
 12. *Desmarres*: Concave metal mirror single sight hole. Maker: Charriere, Paris. Loaned by Dr. Haskett Derby, Boston.  
 13. *Desmarres*: Concave metal mirror with two sight holes. See Plate III, Fig. 39. Maker: Charriere, Paris. Loaned by Dr. B. Joy Jeffries, Boston.  
 14. *Desmarres*: Two openings; metal mirror; similar to 13. Loaned by Dr. C. F. Clark.  
 15. *Pocket Ophthalmoscope*: Concave mirror, with metal protecting cover; the cover is attached to the mirror by a hinge, and

when open is used as handle. Makers: Messrs. Curry & Paxton, London. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

16. *Argyll-Robertson Ophthalmoscope*: Made by Gardiner in Edinburgh, 1878. The whole is about the size of a large flat pillbox, of which the mirror forms the lid; the box contains a convex lens; very compact. Loaned by Dr. A. W. Stirling, Atlanta.

17. *Pocket Ophthalmoscope*: According to Donders: Very compact, similar to 16. Loaned by Dr. Dudley Reynolds, of Louisville, Ky.

### Binocular Ophthalmoscopes.

1. *Giraud-Teulon Binocular Ophthalmoscope*: Made by Nachet, Paris. See *Annal. d'oculist*, 1861. *Cong. méd. de France*, 1863. *Annal. d'oculist*, 1867. See Plate III, Fig. 53. Loaned by Dr. G. Strawbridge, through Messrs. Bonschur & Holmes, of Philadelphia.

2. *Giraud-Teulon*: Made by Nachet, formerly in possession of Dr. Metz, of Massillon. Loaned by Dr. E. P. Morrow, Canton, Ohio.

3. *Early Giraud-Teulon*: See Plate III, Fig. 97. Loaned by Dr. C. H. Williams, Boston.

4. *Lawrence's Binocular Ophthalmoscope*: Modification of Giraud-Teulon. Makers: Murray & Heath, London. See Plate III, Fig. 45. Loaned by Dr. B. Joy Jeffries, Boston.

5. *Giraud-Teulon*: Old form. Loaned by Dr. Callan, of New York, through Mr. E. B. Meyrowitz.

6. *Giraud-Teulon Binocular Ophthalmoscope*: With spectacle attachment. Loaned by Dr. Casey A. Wood.

7. *Lawrence's Binocular Ophthalmoscope*: (Modification of Giraud-Teulon) made by Grunow. Formerly property of Dr. Noyes. Loaned by Dr. D. W. Hunter, New York.

5. Three interchangeable discs. Described in *Trans. Am. Ophth. Soc.*, 1869, p. 47. See Plate V, Fig. 73. Made by Hunter. Loaned by Mr. Alex. Shaw, New York.

6. Three discs similar to 5. Loaned by Dr. C. H. Williams, Boston.

7. Slight modification of 5. Three discs. European make. See Plate V, Fig. 80. Loaned by Dr. Harry Friedenwald, Baltimore.

8. Similar to 7. European make. See Plate V, Fig. 77. Loaned by Dr. Dudley Reynolds, Louisville, Ky.

9. Three interchangeable Rekoss discs with *Wadsworth Tilting Mirror*. See *Boston Med. and Surg. Journ.*, 1877, p. 105. Maker: H. W. Hunter, New York. Loaned by Dr. Wadsworth, Boston.

10. Single disc (12 concave lenses, 12 convex lenses). Tilting mirror. See Plate V, Fig. 19. Loaned by Messrs. Tiemann & Co., New York.

11. Early model. Disc contains two concentric rows of lenses and can be pushed up and down on handle; mirror fixed and not tilting. Made by Hunter, New York. See Plate V, Fig. 62. Formerly in possession of Dr. Noyes. Loaned by Dr. D. W. Hunter, New York.

12. *First Form of Loring Tilting Mirror*: See Plate V, Fig. 64. The little metal plate seen above is placed on the mirror to reduce the size of the latter. One Rekoss disc with two rows of lenses, as in 9, moved by cog-wheel. Made by H. W. Hunter, New York. Formerly property of Dr. Noyes. Loaned by Dr. D. W. Hunter.

13. *Earliest Form of Sector*: See Plate V, Fig. 72. Loaned by Mr. Alex. Shaw, New York.

8. *Lawrence's Binocular Ophthalmoscope*: With Loring Tilting Mirror. See Plate III, Fig. 57. Made by Bonschur & Holmes, Philadelphia. Loaned by Dr. H. I. Jessop, through Messrs. Bonschur & Holmes, Philadelphia.

### Electric Ophthalmoscopes.

1. *Schweigger's Electric Light Ophthalmoscope*: See *Helmholtz Festschrift*, 1889. Maker: Sydow, Berlin. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

2. *Dennett's*: Shown in drawing. See *Transact. Amer. Ophth. Soc.*, 1885 and 1886.

3. *Meyrowitz's*: Attachable to any Loring Ophthalmoscope. Loaned by Mr. E. B. Meyrowitz.

4. *Wolff's Ophthalmoscope*: Received too late for exhibit. See *Zeitschrift fuer Augenhelkunde*, February, 1901.

### Refracting Ophthalmoscopes.

#### LORING.

1. Mirror not tilting, early model. See Plate V, Fig. 44. Loaned by Dr. B. Joy Jeffries, Boston.

2. Early model, one Rekoss disc. See Plate V, Fig. 17. Made by Messrs. Tiemann & Co., New York. Loaned by them.

3. Early model. One Rekoss disc exposed. Mirror not tilting. See Plate V, Fig. 18. Made and loaned by Messrs. Tiemann & Co., New York.

4. Early model. See Plate V, Fig. 16. Made and loaned by Messrs. Tiemann & Co., New York.

14. *Latest pattern*, as made by Messrs. Bonschur & Holmes, Philadelphia. See Plate V. Loaned by Messrs. Bonschur & Holmes.

15. *Latest form*, as made by Mr. E. B. Meyrowitz. Loaned by Mr. Meyrowitz. See Plate V.

16. *Latest model*, as made by Messrs. Chambers, Inskeep & Co. See Plate V.

#### ROTH.

1. Refracting Ophthalmoscope: Modification of Loring's latest. The revolving sector is replaced by a plate containing three lenses which moves automatically. Described in *Klin. Monatsbl. f. Augenh.*, 1894. See Plate V. Loaned by Mr. E. B. Meyrowitz.

2. Improved model. Loaned by Mr. E. B. Meyrowitz.

3. Loaned by Messrs. Chambers, Inskeep & Co.

#### KNAUER.

1. Refracting Ophthalmoscope: Two discs forming all combinations automatically. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

2. Loaned by Mr. E. B. Meyrowitz, New York.

#### KNAPP.

1. *Knapp*: Two discs, the upper has one aperture and 13 concave lenses; the lower, one aperture and 13 convex lenses. The discs overlap. See *Archives of Ophth. and Otol.*, Vol. III, No. 2, 1874. Loaned by Surg. Gen. Museum, Washington.

2. *Small Knapp Ophthalmoscope*: Single disc for lenses. Makers: Messrs. Tiemann & Co., New York. Loaned by them.

3. *Small Knapp Ophthalmoscope*: Single disc, one opening and

23 lenses, flat mirror. See Arch. of Ophth. and Otol., Vol. IV, No. 1, 1874. Loaned by Dr. H. Knapp, New York.

4. *Knapp*: Large disc ophthalmoscope, with crystal lenses. Disc 2 inches in diameter, containing 16 convex and 16 concave lenses, and one opening. Loaned by Dr. H. Knapp, New York.

#### KEYSER.

1. Very small refracting ophthalmoscope. See Phila. Med. Times, 1887-8, Vol. XVIII, p. 167. Loaned by Dr. Wm. Thomson, through Messrs. Bonschur & Holmes, Philadelphia.

#### HARLAN.

1. Combination of Loring, Knapp & Noyes. Two discs superimposed, one rotated by serrated edge, the other by cogwheel. Loaned by Messrs. Bonschur & Holmes, Philadelphia.

#### HIRSCHBERG'S.

1. See Deutsch. Zeitsch. f. Prak. Med., 1877, p. 353. Two Rekoss discs. Three mirrors, one large plane mirror, one large concave mirror, one small plane mirror set at angle. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

#### DUDLEY.

1. Two discs, one containing + lenses, the other — lenses; slightly decentered axes, so that one is moved on one side, the other on the other side of the mirror. Loaned by Dr. Dean.

#### DEWECKER.

1. DeWecker's Ophthalmoscope. One disc with 11 + Spher., and 13 — Spher. lenses. Similar to Loring's one disc Ophthalmoscope. Loaned by Dr. Casey A. Wood.

2. One disc with 20 lenses from + 0.5 to + 10 D. Converted by slide containing — 10.5 D. into — 0.5 to — 10 D. Loaned by Dr. C. H. Williams, Boston.

#### Refracting Ophthalmoscope.

1. Two small mirrors (concave and plane) reversible. Two revolving discs moved by cogs, one containing 10 convex, the other 10 concave lenses. Author not identified. French model. Loaned by Dr. F. M. Chisolm, Baltimore, Md.

#### Jessop's Pocket Refraction Ophthalmoscope.

1. See Brit. Med. Journ., 1887, pt. 2, p. 724. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

*Howe's Pocket Refracting Ophthalmoscope*: See Am. Journ. of Ophth., February, 1893.

1. Very compact. Loaned by Dr. Lucian Howe, Buffalo.

#### Refracting Ophthalmoscopes with Cylindrical Lenses.

1. *Burnett's* Modification of Loring's Ophthalmoscope. Two mirrors; attachment for cylindrical glasses. See Amer. Ophth. Society, 1885, p. 589. Loaned by Dr. Shallerson, through Messrs. Bonschur & Holmes, Philadelphia.

2. *Callan's* Ophthalmoscope, with Stokes constant axis cylinder. Loaned by Dr. Callan, through Mr. E. B. Meyrowitz.

3. *Parent*: Ophthalmoscope. Early form, with Wadsworth mirror. Loaned by Dr. Casey A. Wood, Chicago.

4. *Parent*: (Old pattern.) Loaned by Mr. E. B. Meyrowitz.

5. *Parent*: Contains spherical and cylindrical correcting lenses. See Rec. d'Ophthal., 1883, p. 628. Loaned by Dr. C. M. Culver, Albany, N. Y.

6. *Parent*: Made by Chambers, Inskeep & Co. Attachment with cylindrical lenses. Loaned by Dr. Casey A. Wood, Chicago.

#### Boeckman's Combination Trial Case and Ophthalmoscope.

1. The instrument consists of a handle and three forks into which the circular mirrors and the correcting glasses of small trial case can be placed. Very simple. Loaned by Dr. Boeckman, of St. Paul, Minn.

#### LANDOLT.

1. Early pattern. Loaned by Dr. Zimmerman, through Messrs. Bonschur & Holmes, Philadelphia.

2. Late model. See Bull. Soc. de Chir. d. Paris, 1876, Vol. II, p. 359. Loaned by Dr. Wm. Thomson, Philadelphia, through Messrs. Bonschur & Holmes, Philadelphia.

3. With Wadsworth Mirror. Loaned by Dr. Bane.

4. With Tilting Mirror. Loaned by Dr. Fox, through Messrs. Bonschur & Holmes.

#### FOX.

1. Early model. Loaned by Dr. Webster Fox, through Messrs. Bonschur & Holmes, Philadelphia.

2. One disc and additional sector. Wadsworth Mirror. Loaned by Dr. Fox, received through Messrs. Bonschur & Holmes.

#### JACKSON.

1. Two vertical slides with + and — spheres. Earliest form. Loaned by Dr. Jackson, Denver, Colo.

2. Improved form, circular tilting mirror. Loaned by Dr. Jackson, Denver, Colo.

3. Latest improved form, Loring tilting mirror. Loaned by Messrs. Bonschur & Holmes, Philadelphia.

#### MORRIS.

1. Modification of Cooper's Ophthalmoscope. Contains chain of lenses instead of Rekoss disc. Also large plane and concave mirrors and small concave mirror set at angle. Made by Curry & Paxton, London. Loaned by Messrs. Tiemann & Co., New York.

2. Modified: Two inclined mirrors, plane and concave. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

3. American form, as made by Messrs. Bonschur & Holmes, Philadelphia. Loaned by them.

#### Skiascopic Mirrors.

1. Small, plane mirror according to Jackson. Makers: Messrs. Bonschur & Holmes, Philadelphia. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

2. Large plane mirror, with pupillometer on back. Maker: Sydow, Berlin. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

3 to 15. Thirteen varied forms of skiascopic mirrors. Made by Messrs. Chambers, Inskeep & Co., Chicago.

16. *Roth's Skiaskop*: With tape and correcting lenses. Made by Sydow, Berlin. Loaned by Dr. Harry Friedenwald, Baltimore, Md.

17 to 23. Seven forms of Brown Pusey's combination Ophthalmoscope and Skiascope. Made by Messrs. Chambers, Inskeep & Co., Chicago. Loaned by Dr. Brown Pusey, Chicago.

**Morbid Changes in the Kidneys with Insufficiency of the Thyroid Gland.**—Blum has found evidences of pronounced interstitial nephritis in 36 out of 46 dogs whose thyroid gland had been removed. The other dogs died almost immediately with symptoms of acute tetany, before the nephritis had time to develop. This is the first time that morbid processes in the kidney have been pointed out as the direct result of the intoxication consequent upon the loss of the thyroid function. The intoxication was evidently connected with the processes in the intestines, and was thus an auto-intoxication.—*Virchow's Archiv*, clxvi, 3.

## EXAMINATION OF A GENITO-URINARY PATIENT BY THE GENERAL PRACTITIONER.\*

FERD. C. VALENTINE, M.D.

Professor of Genito-Urinary Diseases, New York School of Clinical Medicine; Genito-Urinary Surgeon, West Side German Dispensary; Genito-Urinary Consultant, Metropolitan Hospital and Dispensary, and United Hebrew Charities, etc.

NEW YORK CITY.

At the onset it is necessary to avow that the principal object of this paper is to obtain instruction. Through this instruction I hope to make valuable to the general practitioner the methods which study and experience have led me to employ in examining patients whose ailments come within the exclusive genito-urinary specialty. If incidentally to the confessed object it be shown that examination of the majority of genito-urinary patients can well be performed by the general practitioner, the purpose of this effort will be more than attained.

*Family History.*—As in all other diseases, the examination of a genito-urinary case, whatever its character, must begin with the history of the patient's family. Heeding a tubercular heredity, for example, will keep us alert to the greater possibility of a patient so stigmatized to fall a victim to genito-urinary tuberculosis. This is especially likely when he has acquired even a mild form of gonorrhea. At the opposite pathologic extreme we find neurotic proclivities reproduce themselves in genito-urinary neuroses. These may vary from an hysterical bladder to psychic impotence.

The importance which the family history has in all ailments is, however, so well appreciated by all practitioners that it need but be mentioned to recall its weight as a diagnostic and prognostic element, and as a guide to individual therapeutics.

*Personal General History.*—The patient's preceding ailments, whether of a constitutional or local character, are certainly not of minor importance, in view of the impress they may have made upon his resistance. His environment and occupation play a large part in contributing to chronicity and complications. It need but be recalled that a person exposed to malaria, or to the bites of infected mosquitoes, is often obliged to interrupt his treatment for gonorrhea. A book-keeper, standing at a high desk all day, is more likely than others to invite complications involving the scrotal contents. This holds equally, albeit of different etiology, for people engaged in occupations requiring great physical efforts. These mere examples, taken at hazard, will call to mind the many others.

*Genito-Urinary History.*—Precedent syphilis may be the direct foundation for involvement of the urethral adnexa, in which local treatment will be futile, unless supplemented by antiluetic medication. Residua of apparently cured previous gonorrhea must be always suspected. Heed must be taken of their possibly delaying success in the condition under consideration, and also of the possibility of recrudescence of dormant infection and alterations.

The individual history of each attack of a genito-urinary ailment must be minutely recorded, as each detail serves to assist not only in diagnosis, but also prepares one for possible interurrences due to previous ailments, and renders intelligent treatment possible.

The many elements necessary to diagnosis, however,

are too vast for consideration in a brief paper. They are being collated in a book now in preparation, entitled "Gonorrhea and Marriage." This will present them in convenient form and detail what experience has led me to adopt as a method of eliciting and recording them.

Besides, there is no need to dilate upon these matters now, as the general practitioner is conversant with the history of each patient whom he sends to the genito-urinary specialist for examination and suggestions regarding treatment.

### PHYSICAL EXAMINATION.

With these premises we are prepared to now consider, in as much detail as possible, the physical examination of the patient. In doing so, while not unmindful of the pedagogic value of the finer divisions of our present subject, time confines us to the consideration of the gross elements only.

*Preparation of the Examiner.*—Inasmuch as the most frequent genito-urinary diseases are of a contagious character, it is the practitioner's distinct duty to protect himself from that contagion, not only to preserve his professional usefulness, but also to avoid becoming a focus of infection to others. The convenience of observing every physical and chemical aseptic precaution is materially enhanced when the examiner is properly dressed for his work. The ordinary slit of the shirt-sleeves should be extended to reach 2½ inches above the olecranon along the arm, when flexed; the cuff should not be over 3 inches in width. So prepared, the sleeves can easily be folded, leaving the forearms bare well above the elbows. As every infectious step of an examination is followed by cleansing the hands, an inadvertent soiling of the forearm is remedied at the same time. If, however, such contamination occurred upon the sleeve of a shirt or operating-coat, it might be relegated to the time of the usual change of garments. In this interim the spot of infection would be forgotten while complying with the demands of urgent work. Then a nervous patient, apprehensive of the pain which a careful examiner will never give him, may grasp his arm at the infected spot and afterwards rub his eyes with the pus containing gonococci. Again, the surgeon may be troubled with an itching eyelid just at a time when his hands are infected, and nothing would be more natural, unless he had acquired the acme of self-control, than that he almost automatically relieve the eyelid with the infected sleeve.

With the arms bared, the ordinary garments should be protected by a suitable gown and apron, of which a number of desirable forms are made. The observations regarding sleeves apply to the operator's vest and trousers. When a gown or apron are soiled they can be easily slipped off and substituted by clean coverings.

Surgeons so unfortunate as to need aids to sight should not wear nose-glasses during their work. Without reflecting upon any of the devices which make it "impossible for eye-glasses to slip," the fact is, that all with which I am acquainted do slip at the most inopportune moments. The annoyance at the interruption is likely to militate against thoroughness, if the examiner is obliged to continue with defective eyes, or he will, if so engrossed in each effort as he should be, forget himself and replace the glasses with infected hands. For these reasons no attempt should be made to examine a genito-urinary patient unless defective vision be corrected with firm spectacles. But even when the ex-

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section: Drs. Frank Billings, George Dock and J. M. Anders.

aminer is blessed with emmetropia, it is always wise for him to protect his eyes from infection by wearing plain spectacles.

*Preparation of the Patient.*—The ideal examinations are made in all cases early after arising from bed, and before the patient has passed urine. Unfortunately, for self-evident reasons, this is not always possible in private practice. The best substitute, therefore, is to instruct the patient to hold his urine as long as possible before the time appointed for the examination. The other preparations of the patient will be mentioned in each special step of the examination.

*Positions of Examiner and Patient.*—The patient's physical condition permitting, he stands before the examiner. The latter is seated, with his back to the light, which, falling fully upon the patient, reveals many points which might not be discovered otherwise. When the patient is feeble or likely to faint, the examination may be conducted while he is lying on a bed, or, better still, on a firm operating table.

When standing before the physician, the patient is ordered to drop his trousers and drawers to his knees for inspection of the genitalia, the thighs, the abdomen and chest, if need be. The appearance of an eruption on the latter may expose previously unsuspected syphilitic infection. The drawers, shirt and undershirt are then carefully examined.

*Stains.*—These, when present on the garments, will often serve materially as diagnostic guides. Briefly, the most frequent of them may here be described.

The shape is: Circular or ovoid, in urethral discharges; irregular diffusive, in after-dribbling of urine from stricture; shred-shaped or band-like, in seminal discharges.

The edges are: Sharply defined, from excess of urethral secretion; undefined, in dribbling after urination; elevated, in seminal discharges.

The size is: Small, from excess of urethral discharge; large, in dribbling after urination; variable, from seminal discharge.

The color is: Homogeneous throughout, in excess of urethral secretions; darker at center than at periphery, in after-dribbling; deeper in spots, owing to varying thickness, from semen.

When no crass evidences of disease, further than stains on the garments are found, or when they are so commingled as to prevent their distinction, microscopic examination will reveal their character. If the stains have dried, they may be moistened with distilled water and the spot then carefully rubbed upon a cover-glass for staining and mounting.

*Inguinal Glands.*—The most convenient manner of examining these glands is to pass the finger along the inguinal region. Any enlargements, however small, should be recorded, whether they preceded the genito-urinary affection or whether they came after it. The early recognition of their implication may enable prompt treatment and save the patient much unnecessary suffering. The wisdom of heeding enlargements of these glands is graphically portrayed by A. Cooper<sup>1</sup>. In an abstract<sup>2</sup> of his article the following appeared:

In typical cases and when the condition has reached its height a group of glands—from three to six or more—can be felt in each groin. \* \* \* Besides being multiple, the glands are also indolent and separate; that is, they are not painful when handled, and can by palpation be clearly defined

and isolated from the others. They are freely movable beneath the skin, are of moderate size, and more or less hard. Both sides are generally affected, but occasionally one groin alone may be involved, and that not always on the same side as the specific lesion. Although multiple indolent glands form one of the most important features of primary syphilis, it must be remembered that they are not in themselves proof of it, and that an apparently typical condition of the groins is sometimes due to other causes, more especially in persons whose glands are unusually susceptible. Among such cases may be mentioned severe gonorrhea, urethral irritation from too strong injections or other injury, irregular herpes, severe balanoposthitis, and tuberculosis. The diagnosis will depend on the history, on the absence of an indurated primary lesion, and on careful watching throughout the incubation period of syphilis.

Before proceeding further it will be well to note whether there is a discharge of pus from any part of the penis. In such case it will be well to cover the organ with a gauze bandage so that in continuing the examination none of the discharge be carried on the surgeon's hands, to other parts of his own or patient's body.

*Genitalia.*—The scrotum should be inspected and palpated in all its parts. It may be pendulous in a generally debilitated condition; drawn up tightly by fear, or by the reflex influence of a renal disturbance; it may be distended or distorted by hernia, epididymitis, orchitis, malignant or benign diseases of its contents, hydrocele or varicocele. Its integument may be the seat of extended intertrigo, or other skin lesion, from perspiration or drugs. In swellings within the scrotum palpation should be supplemented by transillumination. This can be most satisfactorily done by aid of the urethroscopic light, which will be mentioned later on.

The testicles can be most conveniently palpated by what is tantamount to balancing their lower poles upon the inner tips of each of the ring fingers and passing the thumb-tips along the anterior surface of the scrotum and the index and middle fingers along its posterior surface. The size, shape and consistency of each testicle can thus be easily outlined.

The epididymis can be examined in the same manner at first, and any abnormality more closely studied by taking the testicle in the hand of the opposite side, while palpating the epididymis with the fingers of the hand at the same side.

The spermatic cords can easily be palpated, except when the testicles are tightly drawn up, or when the cords are thickened, or are the site of a large hydrocele. Ordinarily, grasping the testicle with the fingers of the same side and gently drawing it downward, enables the fingers of the opposite hand to palpate the vas deferens and the vessels of the cord.

The prepuce's most frequent abnormalities vary between slight fissures at the muco-cutaneous margin, to pronounced gangrenous paraphimosis. When the foreskin can be retracted, all its parts should be examined for posthitis, chancre, chaneroids, condylomata, etc.

The glans is sometimes found deformed from arrested development, due to a very tight, thick or inelastic foreskin, or from a badly performed circumcision. It may be the seat of the same diseases that affect the foreskin; it may have erosions from inspissated smegma or from small stones formed of urinary salts, or parts may be destroyed by devastating chaneroid.

The meatus in acute urethritis is often much reddened and swollen. This gives its lips a pouting appearance. The meatus may also be the seat of chancre, chaneroid, or condylomata.

2. N. Y. Med. Record, April 27, 1901.

## EXAMINATION OF THE DISCHARGE.

The discharge from the meatus may vary from a free, thick, greenish-yellow, bloody flow, to a mere excess of watery moisture, expressible from the urethra with much difficulty. When the latter obtains, it is well not to rely upon the patient's untaught manner of producing this evidence of disease. To demonstrate the presence of such a minimal excess of moisture, the examiner takes the left corpus cavernosum with the fingers of the left hand, and the right corpus cavernosum with the left thumb. The left little finger is thus turned to the patient's pubis. In so holding the penis, care is taken that neither the thumb nor the fingers project below the corpora cavernosa. The right index finger is then semi-flexed and its middle phalanx pressed through the scrotum to the lower margin of the symphysis pubis. As it is drawn forward it compresses the urethra tightly and so propels to the meatus any excess of moisture.

Fig. 1.—Convenient sleeve for exposing arms for genito-urinary work.

The difference in the color of the discharge, from the stain it makes upon the patient's garments or the cotton he wears upon his glans, is noteworthy. Observations subsequent to verification of these differences, as formulated by Diday, lead to the following conclusions: If the discharge is colorless the stain is starch-like; if opaline, it is grayish; if white, it is a yellow stain; yellow, a green stain; a green discharge, a reddish-brown stain, and if the discharge is red there is a mottled dark-brown stain. In noting the color of these stains, however, heed must be taken of stains that may be due to the color of the injections which the patient has used.

Whatever the quantity of the discharge, a specimen for microscopic examination must be taken by a platinum loop, which has been rendered incandescent in a Bunsen or alcohol flame and allowed to cool. The smallest possible quantity of the discharge so taken is then quickly and as thinly as possible spread upon a

cover-glass, which has been cleaned and drawn through the flame just before use.

The conduct of the specimen merits attention. Thus a urethral discharge is easily spread, a prostatic discharge is inclined to roll itself into large tenuous lumps, as if to defy spreading; a discharge from the urethral crypts and glands forms small obstinate hillocks, and a discharge from the seminal vesicles often conveys the sensation of grit between the loop and the cover-glass.

After the specimen has been taken, it is left under a bell-glass until thoroughly air-dried. With an ordinary urethral discharge this may occur in from 3 to 5 minutes; with very thick prostatic discharges this may require 24 hours. When air-dried the specimen is fixed by drawing it through the flame two or three times.

Fig. 2.—Palpation of kidney. Guyon's method.

While the cover-glass is still warm, a saturated solution of eosin is dropped upon it. It is then held high over the flame until the alcohol of the eosin solution begins to evaporate. The specimen is then washed and rewashed until, stood on edge upon bibulous paper, the water passing from it is entirely colorless. The specimen is then stained for 5 minutes with a 2 per cent. solution of methylene blue. It is then again washed until the water flowing from the glass is entirely free from color. The specimen may then be gently dried with bibulous paper, or, better still, left to dry under a bell-glass. When thoroughly dry it is ready for mounting in balsam for examination and preservation.

The microscopic findings in the discharge may be conveniently arranged into: 1, variation of the normal constituents, such as increased mucus and epithelium; 2, bacteria whose presence may explain the pathologic products, and 3, the pathologic products—pus corpuscles.

in severe cases with blood, and in chronic ones with eosinophile cells.

Naturally the diagnosis is predicated upon the class of bacteria found. And if the discharge is the sole feature of the disease, the treatment of the case is governed by the kind of bacteria discovered. In a general way it may be said that, when the gonococcus is the only provocative element, irrigations with permanganate of potash, as elsewhere described,<sup>3</sup> serve in the vast majority of cases.

But when other microbes are found, resembling, or which perhaps really are, colon bacteria, mercuric bichlorid alone, or combined with potassic permanganate will be required. When the specimen, stained as before described, contains no perceptible bacteria, it will be wise to stain another with carbol-fuchsin, and treat it as are the specimens examined for tubercle bacilli. This precaution may lead to the early discovery of a genito-urinary tuberculosis, before it has invaded the deeper genitalia. A word more regarding the gonococcus. On several occasions I have expressed the view that there are probably numerous forms of the gono-

Fig. 3.—Palpation for prolapsed kidney. Goelet's method. (From *Medical Record*, June 1, 1900.)

coccus. Our present instruments of precision have not yet enabled us to definitely distinguish any such differences. Until they do, further experiments with cultures will probably show that some gonococci flourish on one medium and die on another. When expressing this opinion, purely from a clinician's viewpoint, I was unaware of the work being done by Dr. A. Williams, assistant bacteriologist of the New York Board of Health, who kindly wrote on May 21:

In reply to your note of the seventeenth, I can as yet make only the following statement in regard to work done by me on the gonococcus.

1. Certain gonococci grow well on 2 per cent. peptone agar from the original pus and continue to grow well on this medium after being obtained in pure cultures.

2. Certain gonococci grow poorly upon 2 per cent. peptone agar when planted from the original pus, and immediately after isolation in pure cultures; but after a number of culture generations on this medium, they grow as well as those of the first group.

3. The Irrigation Treatment of Gonorrhea; Its Local Complications and Sequelæ.

3. Certain gonococci do not grow upon 2 per cent peptone agar from the original pus, neither will they grow upon it immediately after isolation in pure cultures unless very large quantities be inoculated. Even then they grow spasmodically on this medium.

This emphasizes the hope that precise differentiation, and through it the selection of the appropriate remedy in each case, is less Utopian than might at first appear. It also tends to explain why in a certain case or series of cases, mercuriol, argentamine, argonin, protargol, etc., will abort a most severe attack, while in others the selected drug fails.

As the scope of the present object, however, excludes therapeutic considerations, except when necessary to

Fig. 4.—Valentine Irrigator. (From the *Irrigation Treatment of Gonorrhea, Its Complications and Sequelæ*. Wm. Wood & Co.)

elucidate a diagnostic measure, we may rest at the above memoranda.

#### URANALYSIS.

Such detail as this division of the present subject merits would make a respectable volume, if nothing were cited but the names of the authors who have written upon it. Therefore, only the merest gross outlines of the urinary examination can here be mentioned. In this the general practitioner's often necessarily rapid work will be considered.

Lest extraneous substances become mixed with the urine it is well to clean the meatus, the glans and the foreskin with cotton soaked in bichlorid (1-6000) before asking the patient to empty his bladder. In ordinary, rough office-work the 3-glass test suffices. For convenience, I have, for a number of years, been using 12-inch ignition tubes instead of the glasses or beakers usually employed. The difference between these tubes and those sold as "Valentine urine-tubes" is only one of price. These tubes, whose clear glass gives the exam-

liner a column of urine easily inspected, has other advantages, which will become evident in further consideration. The tubes hold about 175 c.c. (fl. 3vi).

Whenever possible it is well to conduct an examination after the patient has held his urine for at least three hours. As said before, the ideal examination is made when the patient has not urinated since the night before. For more thorough work it is advisable to order the patient to bring the entire urine for the preceding 24 hours in eight-ounce bottles, each one labeled with his name, the date and the hour at which the urine was passed. A memorandum of the food, drink, drugs, mental and physical exercise taken in the intervals will often explain many abnormalities encountered.

The patient is ordered to pass about 3 ounces—100 c.c.—of his urine into as many tubes as he may need to empty his bladder.

The first specimen may be crudely assumed, in the

Fig. 5.—Valentine Auto-Irrigator.

average case, to contain all the washings from the anterior urethra.

The second and subsequent specimens of this urination may be crassly taken as carrying any abnormal additions that are detached from the bladder-walls.

The last specimen voided may be assumed to contain such additions as can be expressed from the adnexa of the posterior urethra—prostate, seminal vesicles, etc.—and the posterior urethra itself, by the final extrusive efforts—the “coup-de-piston” of Guyon.

Lest a false impression be conveyed to junior practitioners by what is here said about the macroscopic examination of the urine, it must here be emphasized that nothing but the crudest outline is now attempted. For ordinary purposes, however, the plan designated and the inferences adduced will suffice.

Having obtained the specimens, it next behooves us to study the transparency of each one; and then the “floaters” it contains. When this term was introduced

by me it was with the reservation that some of the “floaters” do not float, but sink rapidly or drop to the bottom of the tube. The forms of the “floaters,” their dimensions, their conduct and the pathologic significance of each, merit separate study.

The transparency of the urine may be impaired most frequently by phosphates and pus. When phosphates cause the turbidity, the addition of nitric acid will clear the urine with or without the evolution of gas bubbles. When pus causes the turbidity, a saturated solution of caustic potash added to the urine makes it at first assume a syrup-like consistency. If the tube is then twirled, in a species of imitation of the centrifuge's work, a ropy agglomeration is formed. This, Donné, who devised the test, called “rotzig.” For some reason this German forcibly descriptive adjective seems less gross than its English translation “snotty.” Even the best dictionaries do not give us a more acceptable synonym. The other causes of impaired transparency are subjects for finer examination.

The manner of passing urine is often pathognomonic. Thus the neurasthenia which obtains in the majority of genito-urinary affections may prevent the patient from urinating at all in the presence of others, or even when he suspects that another may know of his attempt to urinate. This, too, may cause interruptions in the force of the stream and in its caliber, or may compel its entire interruption. It may be accepted with Wossidlo<sup>4</sup> than any aberration in the manner of urinating, to indicate a pathologic change in the urethra or its adnexa, must be permanent. The most frequent aberrations, aside from those of neurotic origin, are, difficulty or delay in starting the stream, which indicate prostatic enlargement, deep stricture, or a growth within the bladder; reduction in the size of stream, evidencing stricture; interruption of the stream—“stammering urination”—suggesting prostatic enlargement, a growth or foreign body in the bladder; or, dribbling after urination, possibly due to beginning prostatic enlargement, but oftener to stricture.

In extreme cases dysuria, due to any urethral impediment, may compel the patient to squat on the floor, in order to supplement abdominal pressure with his thighs against the belly, so that he may thus plainly force out the few drops which give but partial relief to his overdistended bladder.

The other physical and chemical characteristics of the urine itself are proper subjects for the practitioner's detailed laboratory work, but their discussion has no place in a mere outlined effort. The same applies to the microscopic examination of the urine. In this connection, however, it will be permissible to note that almost universally too little heed is paid the epithelia found in the urine. As Heitzmann<sup>5</sup> has so frequently demonstrated and as clinicians, I among them, have so often occasion to confirm, the recognition of the epithelia found is, in the majority of cases, sufficient to indicate the location of the disease.

#### FURTHER PHYSICAL EXAMINATION.

In similar rough outlines as the other points are discussed, the further examination of the patient may now be considered. The kidneys are not readily palpable in health. The two ways experience has led me to prefer are:

1. In Guyon's technique the patient is placed upon

4. Wossidlo: Die Stricturen der Harnröhre und ihre Behandlung.

5. Heitzmann: Urinary Analysis and Diagnosis by Microscopic and Chemical Examination.

his back, his head comfortably supported, but his shoulders at no higher level than his buttocks. The knees are drawn up to relax the abdominal walls. The physician's hand of the opposite side is passed under patient's back, until the tips of the fingers are exactly within the lowermost costo-vertebral angle. The patient is ordered to inhale deeply, then to fully exhale; at the conclusion of the latter act the fingers of the hand of the same side are pushed as far as possible beneath the ribs, as closely to the kidney as possible. Then the fingers of the other hand are made to produce sharp contractile motions, giving the kidney a forward impetus. If it is enlarged or displaced the fact is recognized by the fingers upon the abdomen.

When the patient is very thin the kidney may be grasped with one hand, the fingers upon the dorsal region, the thumb on the anterior superficies.

2. Goelet's method<sup>6</sup> is especially applicable in prolapse of the kidney. The patient is placed erect, his buttocks resting against a firm table. The hand of the opposite side grasps his renal region firmly and the fingers of the opposite hand press backward and upward on the same half of the abdominal wall. As the prolapsed kidney is so replaced, it passes between the thumb and fingers of the other hand, and is thus readily recognized.

Fig. 6.—Kollmann and Wossidlo's modification of the Valentine urethroscope.

The capacity of the bladder is approximately gauged by the amount of urine passed in the morning, the patient not having urinated since the night before. A more exact estimate is made by filling the bladder with a boric acid solution to the utmost of comfortable distension and then allowing the solution to escape into a vessel for measuring.

The amount of residual urine is determinable only by catheterization immediately after the patient has expelled all the urine he can, without such aid.

The seminal vesicles can but rarely be felt in health. The patient is preferably placed on his back, as for renal palpation. The left foot rests upon its external margin so that its hollow may comfortably receive the heel of the right. The knees are then well drawn up and the hands lightly laid upon the chest. Previous to placing the patient in this position, the examiner has assured himself that his index finger has no projecting nail and consequently no sub-ungual space. He then coats the finger with the following mixture:

|                           |     |
|---------------------------|-----|
| R. Copal .....            | 2   |
| Venetian turpentine ..... | 4   |
| Sulphuric ether .....     | 100 |
| Collodion .....           | 100 |
| Acetone .....             | 8   |

This dries almost instantly and forms a perfect sheath in nowise compressing the finger or obtunding its tactile sense. The finger so protected is then liberally lubricated. For this purpose I have for the past ten months used Synol soap, first presented to the profession by Goelet in June, 1900. The finger, coated and lubricated, is held aside, while the left fingers take the scrotum and penis out of the way of being possibly soiled with the lubricant. The hairs about the anus are then separated with the other fingers of the right hand, and its prepared index finger inserted into the rectum, not with gyratory motions, but directly upward and slightly to the right. The other fingers are closed upon the palm, and the thumb extended to lie as high up as possible along the left side of the scrotum. The left fingers then release the external genitals, and are curved upon the vesical region, pressing it down towards the examining finger in the rectum. Meanwhile the backs of the closed right fingers press the perineum upwards, while the right wrist is held as straight as possible and the elbow is approached to the level of the table. The finger tip passes the prostate and beyond it, and to its outer sides it encounters the seminal vesicles. When enlarged these are distinctly felt; in health, however, as mentioned before, they are often very difficult to outline.

Fig. 7.—Light-carrier of Kollmann and Wossidlo's modified Valentine urethroscope.

The prostate is explored in the same manner as are the seminal vesicles. It differs, however, in being always discernible, although in very great enlargements its entire outlines may be beyond the finger's reach. There are cases in which the prostate projects further in the direction of the bladder than it does towards the rectum. In these the cystoscope is required for diagnosis.

Cowper's glands are never tangible in health. In disease, however, they project forward in the line of gular ligament and then can be readily felt in the perineum. In some cases the abscess presents as far forward as the peno-scrotal angle. Before its full development Cowperitis is usually felt at only one side of the raphe. The tense general swelling that follows may so extend to both sides as to make the gland originally involved indistinguishable.

It is wise to supplement rectal exploration of the urethral adnexa with gentle massage, so as to express some of their contents. As these escape from the meatus a minute quantity may be taken on two cover-glasses for microscopic examination. These specimens will require much longer time for drying than do those emanating from the urethra. After they have dried one specimen should be stained with eosin-methylene and the other with carbol-fuchsin.

Palpation of the urethra is performed by taking the

penis in the left hand, as outlined in connection with the method of obtaining a urethral specimen. The tips of the right fingers then feel all parts of the palpable urethra; to discern any general thickening of its walls, any localized swelling, e. g., peri-urethral abscess, or the presence of foreign bodies, e.g., so-called urethral calculi.

Previous to sketching examinations that require ingressions into the urethra, it is well to recall the need of aseptic work, which, if anything, is more necessary here than in other parts of the body. While conceding that absolute asepsis of the urethra is not obtainable, this does not excuse omission of any detail that may reduce the danger of carrying infection to uninfected parts. The technique thereof is not difficult, as I endeavored to show in a paper<sup>7</sup> read before this body last year. It may be summed up as follows: 1, cleansing the meatus, glans and prepuce with cotton soaked in bichlorid 1-6000; 2, cleansing the urethra with boric acid by means of the office irrigator, or the easily portable auto-irrigator; 3, filling the cleansed urethra with 5 per cent. iodoform suspension in glycerin, and, after instrumentation, 4, repeating the urethral irrigation.

In exploration of the urethra the soft, flexible bougie-à-boule, with an almost rectangular shoulder, is the only instrument which can serve for tactile exploration. It is the essentially diagnostic instrument; rigid instruments are for therapeutic purposes exclusively. Omitting all argument hereon, it will suffice to remember that many a urethra will easily and smoothly permit the passage of a steel sound of large caliber. But when a properly constructed bougie-à-boule, even one or two sizes smaller, after having been inserted into the urethra, is deftly whipped out of the channel, it reveals impingements which the rigid instrument could not. I repeat, therefore, that a rigid sound or dilator is a therapeutic instrument, while the softer instrument is the only one that can serve for diagnosis.

Urethroscopy with modern devices is now as much a procedure for the general practitioner as it is for the genito-urinary specialist. I may be pardoned for expressing a decided preference for the urethroscope upon whose simplification I have spent much time and study. Briefly described, it consists of a box containing all that is needed for urethroscopy, viz., dry cells for illumination, tubes for various calibers of the urethra, lamps which snugly fit along the urethral tubes, and applicators to carry cotton for cleansing the urethra and for such topical remedies as the conditions found may require.

The newest form of this instrument is the one I have the honor of showing. It is a modification of the Valentine urethroscope, by Prof. Kollmann, Leipzig, and Dr. Wossidlo, Berlin. The original device, as presented by me before this body two years ago, was, as I then emphasized, a modification of the Oberländer urethroscope. Kollmann and Wossidlo further modified this device, rendering it more convenient for its work. These eminent German scientists, in doing me the honor to improve upon this device, did not, however, eliminate my name therefrom. A signal convenience is in the ingenious addition to the case, of a Nitze irrigating cystoscope, whose lamp is of such low tension that the same cells used for urethroscopy can be employed for visual examination of the bladder.

The technique of urethroscopy is self-evident on examination of the instrument. Naturally, to distinguish

the various pathologic conditions some experience is required. But the experience necessary for good diagnostic work is far less than that needed for any other of the instruments of precision, such as the ophthalmoscope, the laryngoscope, etc.

Cystoscopy implies all that has been said of urethroscopy, except that its technique entails considerable training and much practice. It involves catheterization of the ureters in some cases, a process demanding the acme of that skill which experience gives. It naturally is applicable only when the mouths of the ureters can be entered.

Cultures and inoculations are mentioned here only to recall the cases in which, without them, the examination can not be completed. They require elaborate laboratory facilities, which are necessary addenda to the specialist's office, and to which but few general practitioners can devote the large amount of time and attention they demand.

Cryoscopy, as its inventor, Raoult, defines this new method of urinary examination, is "the study of dissolved bodies, based upon the observation of the point of congelation of their solutions." As cryoscopy, however, is a laboratory method, its consideration has no place in a purely clinical study.

#### SUMMARY.

Throughout this effort it has been my desire to emphasize the following points:

1. All genito-urinary examinations should be painless.
2. The operator should conduct no examination unless his arms are bared to above the elbows and his clothing protected by a gown and apron.
3. During every genito-urinary examination the physician should protect his eyes with spectacles—not eyeglasses—even if he has no visual defect.
4. Ideal examinations are made in the morning, before the patient has passed his first urine.
5. The amount and character of a urethral discharge can be estimated only by correct technique in expressing the urethral contents.
6. The color of a urethral discharge changes when it dries upon the patient's garments.
7. The meatus should be cleaned before passing urine for examination.
8. The manner of urinating is often pathognomonic.
9. The epithelia found in the urine are indicative of the locality of the lesion.
10. Examination of the urethral adnexa is a necessary part of the steps for complete diagnosis.
11. No instrumental ingression of the urethra should be attempted without most thorough efforts at rendering it aseptic.
12. The technique of striving at urethral asepsis is neither complicated nor difficult.
13. The soft bougie-à-boule is the only instrument that can be used for tactile exploration of the urethra; it is purely a diagnostic instrument; the rigid sound is wholly a therapeutic instrument.
14. Urethroscopy with a modern instrument is not difficult.
15. The general practitioner is perfectly competent to examine the vast majority of genito-urinary cases.
16. Such examinations only exceptionally require extraordinary skill or a large armamentarium.
17. The pathology of genito-urinary disease does not materially differ from that of other affections.

<sup>7</sup> Surgical Asepsis of the Urethra and Bladder. JOURNAL A. M. A., Jan. 12, 1901.

## THE UNVEILING OF THE CELL.\*

LEWELLYS F. BARKER, M.B.

PROFESSOR OF ANATOMY, UNIVERSITY OF CHICAGO,  
CHICAGO.

In the kind invitation of your secretary to read a paper before this Academy, it was suggested that a subject of general interest be chosen rather than one involving a very technical description of some single especial research. On thinking over the few topics upon which I might with fairness venture to address you, it occurred to me that perhaps one dealing with the newer knowledge of the cell might be as acceptable as any. I have decided to ask you, therefore, to permit me during the next half hour or more, to place before you some examples illustrating the trend of cellular research, to outline to you a few of the results thus far attained, and to indicate along what lines of investigation work is likely to proceed in yielding us the discoveries that the near future has to reveal.

I may be permitted to say in the beginning that I regard the development of the cell doctrine as one of the most brilliant and most important generalizations of the century just passed, as one which has given us a clearer conception of the general organization of animals and vegetables than any which preceded it. I do not wish, however, to be understood as joining the ranks of those extremists who, traveling always on the purely cellular highway, refuse to consider, as practicable or desirable, progress toward a knowledge of structure and function along any other road. To me such a prejudged attitude is but little less condemnable than that of propagandists of another type, who, adding the sin of ingratitude to the defect of hemianopic biologic vision, declare not only that the study of cells in themselves offers no hope for the future of science but also that such study has done little or nothing for it in the past. Both these attitudes are unfortunate; but critical minds, incapable of occupying either, must fain be charitable with the mistakes to which the enthusiasm of special investigation leads. It is perhaps enough that special investigators supply us with new facts and set up for us new theories; if sometimes one of them loses sight of the wood on account of the trees and another, occupied with the wood, forgets that there are trees, we need not despair, for men of a more philosophic turn will from time to time preserve for the majority of us the privilege of seeing both.

According as one looks upon the cell as an elementary organism only, or as an integral and determined part of a higher organism only, he will tend to gravitate to the one or the other pole of partisanship; it is only when he recognizes that the cell occupies a double position that the investigator is likely to keep his mind in that equatorial plane in which justice can be done to each of the two views.

Purely cytographic studies have, since the work of Schleiden and Schwann in histology and of Virchow in pathology, steadily progressed in volume and in penetration until one wonders if the limit has not almost been reached. That this is not the case, is, however, evidenced by the fact that the journals continue to pour out cytological articles, and new monographs deal with the problems concerned are more numerous than ever. The cytological school, which, especially with the chromosmium-acetic mixture, did so much to give us data concerning the characters of nuclei and the changes which they undergo during division, has been followed

by another group of investigators who, using sublimate and other fixing reagents and finding centrosome and archiplasmic radiations in the protoplasm have constructed theories of protoplasmic structure which exceed in intricacy the doctrine of the chromosomic architecture of the nucleus. Again, the method of Golgi has given us an entirely new conception of the extent and complexity of branching to which the protoplasm of certain of the cells of the body is subject; and a host of special methods have been devised to demonstrate special features in the cells of the various tissues of the body.

Opinions as to ultimate structure have, as everyone knows, been most disparate and the champions of the granule-theory, the thread-theory, the sponge-theory, the foam-theory, vie with one another for supremacy. Physiologists, like morphologists, indulge in conceptions of plasomes, biophores, pangenes, micellæ, bionten, and physiologic units of other sorts intermediate between the cell as a whole and the ultimate chemical substances of which it is made up. One of the important advances recently made consists in the general recognition by histologists of the necessity of distinguishing sharply between the constituents of the cells as they actually exist in nature and the modifications of these which are to be met with in the rigid, stained or unstained cadavers of cells which we study under the microscope in ordinary histological fixed preparations. Thanks to the researches of many men in many lands and especially, recently, to those of the botanist Fischer of Leipzig, we have been made to realize what we have known all along but did not fully appreciate that, when a fixing reagent acts upon a cell, changes occur which in a physical and chemical sense are of a very gross type, fully as gross as those involved in the transformation of a raw egg into a hard-boiled one. These changes vary with the character and concentration of the fixing reagent employed, and with the nature of the substance in the cell acted upon. Thus it has been shown that substances like serum, serum globulin, nucleo-albumin, and nuclein, when in solution are precipitated by various fixing reagents in a *coagulum* of some form, while substances like deutero-albumose, proto-albumose, peptone, nucleinic acid and hemoglobin tend to be thrown down in the form of *granules*—the thinner the solution, the finer and more regular, as a rule, the character of the granulation.

Curious results have been obtained by Fischer on injection of pith with solutions of albumose or other substances and subsequent fixation. On microscopic examination of sections of the pith he could demonstrate exquisite granule- and coagulum-pictures, some of which were almost indistinguishable from the appearances of centrosome and archiplasmic radiations occurring in ordinary cells.

As a consequence of these investigations, there has, and with right, been a strong reaction against those views which strive in spite of apparently irreconcilable contradictions to conceive of the structure of living protoplasm as being monomorphous. The "living substance" as contrasted with the "non-living" paraplast is presupposed in Altmann's doctrine, in Flemming's, in Bütschli's, to be of some form, alteration of which is incompatible with the maintenance of its life. Berthold's theory alone, as Fischer has emphasized, is consonant with a conception of a polymorphism of the protoplasm, since his idea of an emulsion is not irreconcilable in its presuppositions with changes in morphology. Berthold himself believes that mikrosomes, which may be some-

\* Read before the Buffalo Academy of Medicine, Nov. 19, 1901.

times solid, amorphous or crystalline deposits, sometimes drop-like formations, are like vacuoles, oil droplets, etc., to be regarded as products of "separation" in the protoplasmic emulsion. In such instances there would be polymorphous pictures during life as well as after fixation. On the whole it is fair to say that there is a growing belief in the polymorphism of protoplasm and in a protoplasmic constitution represented in large part by substances in colloidal solution.

The scramble to escape from the tumbling edifice of the monomorphists has in some quarters amounted almost to a panic. Some of the former occupants are willing not only that the structure should vanish as rapidly as possible, but would gladly deny ever having had any connection with it, and especially ever having received any benefits from it; some indeed would go so far as to discredit even every tool utilized in the construction and to hint that the methods of the microscopic cytologist are doing nothing and never will do anything to help solve the problems of living organisms! If in fixed preparations we have to deal merely with precipitates and coagula, then how, they ask us, can the microscopic pictures of these things be of any value to us? But here a calmer consideration of the situation will save us from so gross an injustice. One has only to recall the practical benefits derived from histologic and cytologic studies of fixation pictures to immediately realize that the studies in which they have been employed have been richly rewarded. Nissl's idea of the constancy of what he calls "equivalent pictures" is here of distinct value. The details of the phenomena of inflammation, degeneration and regeneration, or of tumor-formation could never have become known without these methods. The degree of malignancy of a tumor can often be directly determined by a microscopic examination of its elements. Our knowledge of that great group of diseases in which alterations in the number and character of the corpuscles of the blood occur has been built up largely through cytologic study. The studies on the classification of bacteria, the development of bacteriology in general, and particularly the investigations on the relation of bacteria to cells of the body owe a large debt to the same methods. So many important examples will immediately leap to the eyes of any one who will give the subject a little careful thought that further comment in this direction is unnecessary.

Another side of the subject, not often enough dwelt upon, but of no little significance for the future, ought to be pointed out here. I refer to the advantages derivable from a study of micro-chemical reactions. The study of microscopic histology is likely, it seems to me, to resolve itself more and more into this. Even if the protoplasm of a cell consists only of chemical substances of a greater or less degree of complexity, and the prevalent ideas of its organization be baseless—I do not say that they are—one of the best means of studying it will be by combining microscopic observation with the methods of analytical chemistry. Who would assert that the precipitates producible by various chemical substances in solutions of albumin, of copper sulphate, or of silver nitrate are of no interest to the chemist as regards the nature of these solutions? Is it any more true that the precipitates and coagula formed by means of others can be of no help to us in investigations on the nature of cells? I think not, nor do I see how any one familiar with the beautiful experiments of Fischer on the micro-chemical fixation-analysis for albumoses and nucleic acid or the important deductions made by R. R. Bensley concerning the glands of the stomach, or the researches

of A. B. Macallum upon the distribution of iron and phosphorus in animal and vegetable cells, to choose only three of many striking examples, can entertain the idea for a moment.

A large portion of the confusion which has arisen in the minds of investigators is due to differences in conception with regard to the meaning of organization. Everyone is clear as to the application of the word to the structure of complicated higher organisms but ideas become hazy when the structure of unicellular organisms is thought of. There are many who think that we have an infinite series of gradations of complexity of organization and that the view expressed by Nägeli in 1884 that everything in the world, even what hitherto we have designated as "inorganic," possesses organization in a higher or lower degree, has much in its favor. When men like Darwin, Spencer, Weismann, de Vries, Pfeiffer, O. Hertwig and Roux have supported views which are based upon the idea that the secret of the ultimate constitution of living organisms must be sought in some hidden organization, that function is explicable only by the assumption of the harmonious co-operation of certain ultimate units in the cell and that these units work together like the parts of a machine, one naturally hesitates to summarily reject these hypotheses.

On the other hand, there is much that appeals to the speculative mind in the other view in which instead of hypothecating a machine-like organization of the ultimate constituents of organisms, a chemical organization of these constituents is assumed. The truth may here, as it does in so many cases, lie in a compromise between the two views. It may very well be that, since in large part at least the capacities of an organism depend in the ultimate analysis upon chemical energy, the energy which runs the machine is not simply brought to it, but is actually produced within the machine itself. At the same time, as Bütschli points out, there would seem to be no reason why a great significance should not be ascribed to the formal structure-relations in explaining the peculiar phenomena which organisms present. In so doing, as he says, it is not necessary to assume that these structural relations form an unbridgeable chasm between the "organized" and the "unorganized"; on the contrary, structures agreeing in principle with them are probably to be found in the inorganic world, those occurring in organisms being only farther developed and more complicated on the one hand and on the other endowed with especial capacities owing to the special chemical nature of the substances constituting them; one is reminded at once of the peculiar properties of certain purely physical structures, and of other chemico-physical structures (micro-crystalline structure, imbibition phenomena, properties of sphäro-crystals, mobility of oil-soap foams, etc.).<sup>1</sup>

Whatever may finally be decided upon, certain it is that noteworthy progress is being made just now in the study of the cell through investigations in which the attempt is made to apply the laws of physics and chemistry to the phenomena of cell-life. Indeed, the harvest reaped by Ludwig and his pupils in the field of organ-activities and apparatus-mechanisms promises to be succeeded by a still more profitable yield in the domain of the cell-activities underlying them. Time will not permit me to do more than to refer to two or three of the more striking series of achievements. The studies of fermentation, of certain organic and inorganic intoxications, of antitoxin formation and the production of immunity, will serve as examples.

1. Bütschli O. Mechanismus und Vitalismus, 1901.

Out of the vagueness of earlier conceptions there have been gradually evolved more precise ideas of ferments and of the process of fermentation. To quote Carl Oppenheimer, "a ferment is the material substratum of a peculiar form of energy which is produced by living cells and is more or less firmly attached to them, though the part it plays in the vital process is not so bound; this energy is capable of liberating latent (potential) energy of chemical substances and of transforming it into kinetic energy; the effect is such that when the chemical substance is altered, the substance newly formed or the sum of newly formed substances possesses a smaller potential energy, i. e., a smaller heat of combustion than the original substance. The ferment itself remains unaltered during the process. It acts specifically, i. e., each ferment is active only upon substances of wholly definite structural and stereo-chemical arrangement." Or to quote J. Reynolds Green, by fermentation is meant "the decomposition of complex organic material into substances of simpler composition by the agency either of protoplasm itself or of a secretion prepared by it." These are the definitions given in two of the most recent books dealing with the subject, one published in 1899 and the other in 1900. So rapidly is the subject moving that, as will be pointed out farther on, it seems quite probable that each of these definitions may have to be modified. One of the greatest achievements in connection with fermentation since Pasteur's time is undoubtedly the proof brought by E. Buchner that the fermentative activity of the yeast cell, so long inseparably connected with the life of the cell, is the property of an enzyme which he calls *zymase* and which can, when expressed from the cell, change glucose into alcohol just as well as the original yeast. Here at a blow fell down the partition between the so-called "organized ferments" and the "unorganized ferments" or enzymes. The fact appears to be that some ferments in nature act chiefly within the cells in which they are formed (*zymase*) while others are thrown off into the environment of the cell to carry on their work outside it (secreted enzymes, "unorganized ferments").

I have had occasion, during the last few months, to review some of the recent literature on ferments and have been astonished to find in how many instances and in what divers processes the proof of ferment participation appears to have been brought, and to learn how extensive and penetrating have been the researches dealing with their nature and mode of action. Aside from alcoholic fermentation and the prodigious labor of Hansen and others on the different species of yeasts and their bearing upon the industrial methods of brewing and the manufacture of wine, one is much impressed on approaching the subject seriously for the first time, by the progress made in connection with the saccharifying ferments, the ferments which split up glucosids and the various proteolytic and coagulum-producing enzymes. The oxidizing ferments or oxidases which seem to play so large a part in the processes of vegetable life, are in all probability of just as great significance in the life of animal cells.

Most fascinating in connection with the ferments are the experiments and hypotheses of Emil Fischer, who, so well known in connection with his work on the stereo-chemistry of the sugars has during the past three or four years been devoting his attention also to a stereo-chemical consideration of the ferments. Pasteur had made the remarkable observation that fungi are capable of fermenting the dextrorotatory tartaric acid, not the levorotatory. It has also been known for a long time that in the fermentation of sugars by yeasts only those sugars

ferment which contain 6 and 9 carbon atoms in their molecules (and of the latter only those belonging to the "d" series, and indeed not all of them). Sugars of identical chemical composition may or may not ferment according as the spatial relations of the atoms to one another in the molecule conform to one or another configuration. Fischer has undertaken to investigate the stereo-chemistry of the enzymes proceeding on the hypothesis that for a particular stereo-chemical configuration of a sugar there must be a corresponding particular stereo-chemical configuration of the enzyme which is capable of fermenting it—in other words that the relation of enzyme to its fermentable sugar is something of the nature of the relation of a key to the chambers of a lock. Fischer prepared artificially various derivatives of the sugars like glucosids or alcohol-sugar ethers. On submitting these to the action of ferments he found that the ferment of yeast and that known as *emulsin* acted only upon the glucosids which correspond to the sugars fermentable by them and not upon glucosids of the same chemical composition but of different stereo-chemical configuration. Further, from the fermentable sugars it is possible to prepare two stereoisomeric series of glucosids, so-called alpha-glucosids and beta-glucosids and of these Fischer discovered that the members of the alpha-series are fermentable by the enzymes of yeast only (maltases and invertases), while the members of the beta-series are split only by *emulsin*—an exquisite example of the specific effect of enzyme action. But, on the other hand, this specificity is not dependent upon the molecule as a whole, as is shown by the fact that the influence of an enzyme is not confined exclusively to a single chemical substance. Diastase is capable of splitting all starches and a part of the dextrins. *Emulsin* can split up numerous natural glucosids of varying composition (amygdalin, salicin, arbutin, etc.) as well as the beta-series of artificial glucosids prepared from fermentable sugars. The proteolytic enzymes (pepsin and trypsin) can split up the great group of albuminous substances though, as is well known, different members of the group must be very differently constituted chemically. The specificity of the action of the ferment obviously must concern therefore a certain spatially arranged group of atoms in the molecule; no matter then, what the size or total composition of the molecule, its splitting by a given ferment is conditioned by its possession of the steric atomic group corresponding to it. The fact that certain substances are split by different ferments in different ways supports rather than detracts from the validity of the theory. Amygdalin, the glucosid present in bitter almonds, is split up by both *emulsin* and the yeast enzymes (maltases and invertases) but in an entirely different way. The yeast enzymes split off only one molecule of glucose and leave behind the remainder of the glucosid in the form of a peculiar body known as mandelonitrilglucosid. *Emulsin* on the other hand splits up amygdalin into benzaldehyd, hydrochloric acid and glucose. While mandelonitrilglucosid is insusceptible to further action by yeast ferments, it can be split up by *emulsin* further into benzaldehyd, HCl and glucose. Thus while the yeast-ferments can unlock, as it were, only the outer door of the molecule, entrance to the inner compartment can be gained, apparently, only with the aid of the *emulsin* pass-key.

With such wonderful phenomena before us, it is but little wonder that speculation is rife with regard to the

nature of what we call ferments and enzymes, for any distinction between the two may theoretically, at any rate, from now on be dispensed with. It does not seem profitable to go into a full discussion of the topic on this occasion. The difficulties in coming to a decision are very great. For the view that the ferments represent actual chemical substances a very great deal can be said; the specific effects of enzymes speak in favor of a specific material substratum. On the other hand the theory of Arthus that enzymes represent simply non-material centers of energy has some adherents. Attempts at preparation of enzymes as pure chemical substances have thus far been fruitless; and if they are chemical substances, they are quite different from anything we know as yet in the inorganic world, if certain substances acting "katalytically" and the so-called inorganic ferments (spongy platinum) be excluded.

Some very recent work strengthens markedly the position of those who espouse the chemical theory. I refer to the experiments of Croft Hill and of Kastle and Loewenhardt on the reversibility of ferment action. In 1898 Hill asserted to the astonishment of the scientific world that maltase, which ordinarily splits a molecule of maltose into two molecules of glucose, can, under certain circumstances (concentration of the solution), turn about and act in the opposite direction, a certain amount of glucose combining to reform maltose. In some quarters Hill's findings have been received with great skepticism, Oppenheimer especially tending to discredit Hill's interpretation of the phenomena he met with, and asserting that even if it were confirmed it would put maltase in a wholly exceptional position, separate from other enzymes. A large part of Oppenheimer's objections to Hill's work would seem to be his assumption that such a reversibility is impossible; it is out of accord with his definition of a ferment (*vide supra*) and his objection is in a sense a *petitio principii*. Though Green's definition is also incompatible with Hill's work, possibly having been formulated before he was familiar with it, the English author accepts Hill's results enthusiastically, looks upon them as bringing ferment action into accord with the general theory of chemical equilibrium or mass action, and as increasing the credibility of the chemical hypothesis. To the delight of many, Hill's observations and conceptions have received striking confirmation in the work of two American investigators—Kastle and Loewenhardt, of Lexington, Kentucky. With an entirely different enzyme, viz., lipase, the fat-splitting enzyme, they appear to have been able to demonstrate a very definite reversibility of action, and a flood of new light is thrown at once upon the problem of fat absorption and fat translocation. Further experimentation along these lines with the same and other enzymes will be eagerly awaited.<sup>2</sup>

Let us now turn to the consideration of another series of problems which concern the cells of the body, namely those dealing with the effects of certain poisons upon the constitution of the cells and with the cellular activities which lead to the production of antitoxins (Behring, Ehrlich) and various anti-bodies, among others the bacteriolysins (Pfeiffer), the anti-complements (Ehrlich),

the hemolysins (Ehrlich), and other cytolytins (Bordet). This subject is a very large one and I realize that in the time available I can do no more than sketch very briefly and in coarsest lines its most salient features. The work which has been done is, however, so brilliant, and fits in so neatly with the investigations on the enzymes, and, moreover, its results carry with them so much hope for the future of pathology and therapy that I can not deny myself the pleasure of referring to it here.

Just as Emil Fischer, as the basis of his views on the nature of ferments, has made the stereochemical configuration of certain atomic groupings in the molecule of the greatest significance, so Ehrlich, in his studies of toxins and antitoxins has applied similar stereochemical conceptions. He believes that the specific affinity of a toxin for an antitoxin can be most simply explained by the assumption of two atomic groups which correspond to one another in configuration. As a result of a large number of experiments he has concluded that the toxin molecule (*e. g.*, diphtheria toxin or tetanotoxin) possesses at least two combining groups. Diphtheria toxin and tetanotoxin are toxic products of secretion, but closely related to them are certain vegetable poisons like ricin and abrin, and certain poisons of animal origin like snake venom and the hematoxins present in the sera of normal animals (*e. g.*, ichthyotoxin of eel serum). Toxic bodies of this class differ from poisons like the alkaloids and toxic glucosids in that they are capable of producing antitoxins. Even morphin, to which great tolerance, as everybody knows, can be developed, does not, it is said, give rise to the production of anti-bodies, but leads to increased oxidation capacity of the cells, by which the excess of morphin is destroyed. Ehrlich believes, therefore, that alkaloids, antipyretics, aromatic amines and anilin dyes when introduced into the body form only very loose combinations with certain of the cells of the tissues instead of being anchored there by a firm synthesis, and it would appear from his and other investigations, that in the brain especially it is lecithin and similar fat-like bodies which account for the accumulation there of alkaloids and similar substances. Toxins, on the contrary, Ehrlich thinks, form a much more permanent and firm combination with the protoplasm, entering actually into its constitution by a process of assimilation quite like that underlying the nutrition of the cell by food substances. To explain the assimilative processes in cells and to account for the firm chemical syntheses by which they are accomplished, Ehrlich has suggested that "protoplasm is equipped with certain atomic groups, whose function especially consists in fixing to themselves certain foodstuffs of importance to the cell life." These atomic groups he speaks of as "side chains" or "receptors," and he assumes that the foodstuffs for which these side chains have a maximal chemical affinity must contain atomic groupings of similar stereochemical configuration.\* It is only a step farther to his conception of the mode of action of toxins. One of the two combining groups of the toxin molecule corresponds to foodstuffs in being able to unite with the receptors of definite cells; this is designated, therefore, a *haptophore* group, and the receptors may be considered as a toxophile group. The other group of the toxin molecule, called the *toxophore* group, is the one which injures the protoplasm, although it can affect the latter only through the *haptophore* group. From the researches of Konitz and Heymans, it appears that the

2. Nef's conception of the mode of action of enzymes is most interesting. Basing his view upon a long series of experiments in the so-called "methylene chemistry," he assumes that catalytic agents, among them enzymes, act by depressing the temperature of a dissociation process by which compounds containing tetravalent carbon are split up into two or more substances, one of which contains carbon in a bivalent condition and is therefore very unstable, uniting with oxygen, water or other available substance to form a new compound. It is his opinion that a large proportion of both analytical and synthetical reactions will ultimately be explained in this way.

\* I am indebted to Dr. Preston Kyes for much information with regard to Ehrlich's views.

haptophore group becomes *immediately* active when the toxin is injected into the organism, the poison combining at once with the cells which have corresponding receptors. The toxophore group, however, is often very slowly active, a longer or shorter incubation period elapsing after injection before the specific toxic effects become evident. The toxophore group would seem to be far less stable than the haptophore group; it can be destroyed without injury to the haptophore group, in which case a toxin is converted into a toxoid. Moreover, as Morgenroth has shown, the activity of the toxophore group of the tetanus toxin is inhibited by low temperature, while the haptophore group is not, a view quite in accord with Courmont's observations that frogs kept at a temperature of 20° C. show no signs of tetanus, even after large quantities of toxin are injected, though they quickly succumb in a warmer environment. Tetanus toxin in the mouse appears to combine only with nerve cells. This may be explained by assuming that receptors of the proper sort are present only in the nervous system of this animal: in other words, the localization of toxins in organisms is probably to be explained upon the possession by the variously differentiated tissues of specific combining powers. The number and distribution of specific receptors may be called upon to account in part, at least, for the variations in lethal dosage and for the distribution of the lesions in the tissues in different infections and intoxications.

Ehrlich's explanation of the origin of antitoxins is easily grasped if the theory thus far has been followed. When receptors which ordinarily unite with a foodstuff combine with the haptophore group of a toxin, there results a defect in cell life, since the receptors are thrown out of their normal function. If Weigert's theory of regeneration is correct, the cells will not only build new receptors to repair the defect, but the regeneration will go far beyond the necessary limit—"over-compensation" being the rule. By suitable dosage of toxin, the amount being gradually increased, the over-compensation finally reaches a stage in which the excess of receptors or side chains is so great that they are, like useless ballast, thrown off into the blood. According to Ehrlich's theory, the antitoxins are nothing more or less than such free side chains. Each supplied with a group combining with a haptophore group of a toxin is capable of fixing and thus neutralizing one molecule of toxin.

In the production of immunity, it is the haptophore group of the toxin molecule which is essential: the toxophore group is of no significance. If this be true, toxoids or toxins deprived of their toxophore group may be of the greatest importance in future therapy. We have held out to us the prospect of the establishment of an active immunity through the injection of substances which are entirely innocuous.

Some of the difficulties met with by the investigator in connection with toxins and antitoxins are disappearing now that we are being better informed with regard to the life of the bacterial cell. The great complexity of the products of cell activity is gradually becoming apparent and we no longer think of the tetanus bacillus or of the diphtheria bacillus as producing a single poison. On the contrary, it seems very probable that a given pathogenic bacterium may produce several or even a whole series of poisons. Thus the tetanus bacillus has been shown to produce not only the poison which is now called *tetanospasmin*, and which causes the typical convulsive attacks, but also a substance which breaks up red corpuscles and is known as *tetanolysin*. That the haptophore group in tetanospasmin is different from the

haptophore group in tetanolysin is shown by the fact that the receptors of the red blood corpuscles can combine with tetanolysin but not with tetanospasmin. In the production of immunity against tetanus, therefore, it is safe to assume that at least two varieties of antibodies are developed and that each of these has an independent origin in different parts of the body. Besides the production by the same bacillus of different poisons having different haptophore groups there is evidence that some bacilli can produce poisons which possess identical haptophore groups but different toxophore groups. Thus the diphtheria bacillus besides giving rise to the ordinary toxin which is the main poison it produces, also manufactures a second poison called the diphtheria *toxone*. Toxin and toxone are believed to possess similar or identical haptophore groups since both poisons are completely neutralized by antitoxin. The toxin, however, has a lower degree of affinity for antitoxin than has the main toxin, since when an amount of antitoxin insufficient to neutralize all poison present is added to a mixture of the two, the toxin is the first to become saturated, just as when we neutralize a mixture of HCl and  $\text{HC}_2\text{H}_3\text{O}_2$ , the HCl is neutralized first and the acetic acid only later. This makes it probable that the difference between the two poisons lies in the toxophore group, a view supported by the difference in biological effect between toxin and toxone: the former causes the extensive necroses characteristic of this disease, while the latter does not, though it is responsible for the slowly appearing alterations of the nervous system which account for the post-diphtheric paralyses.

As many of you are aware, the side chain theory of Ehrlich can be and has been applied to explain the mode of formation and action of the bacteriolysins of Pfeiffer, the hemolysins and cytotoxins of Bordet, the "coagulins" of Kraus and Bordet, the "agglutinins" of Durham, Gruber and Pfeiffer, and the "antiferments" of von Dungern. It is very interesting, indeed, to have learned that the two components of hemolysin, for example, the "immune body" and the "complement," combine with one another to form the active substance, which appears to be quite analogous to a simple toxin, differing from it only in this, that it is composed of two separate parts, one of which (the immune body) carries the haptophore, the other (the complement) the toxophore group. I need not dwell upon the special features of these bodies, for I am told that Dr. Clowes has already presented the subject to this society, and, moreover, the articles of Ehrlich and others are easily available to those who wish to follow the subject further.

Had I the time—I know I have not—I should like, in contrast to the work done with very complex organic bodies, such as the ferments, foods, bacterial toxins and antibodies, to review the remarkable results which are being obtained with the relatively simpler methods of physical chemistry—results which are cutting large windows in walls hitherto impenetrable between us and animal and vegetable cells. The application to biology of the laws to which the phenomena of osmotic pressure, of chemical equilibrium and of substances in various conditions of aggregation conform, is being crowned with unusual success. One has only to read Ernst Cohen's recent monograph to be convinced that there is a very important future for the principles introduced by van't Hoff and Arrhenius in connection with medical problems. Already some very striking observations have been made and experimentation in this field is most active. It is matter for congratulation that much of the successful work of this kind is

being conducted by American investigators. Loeb, Morgan, Kahlenberg and True, and others are important contributors. Loeb's researches especially on artificial parthenogenesis, and upon the effects of ions of various sorts upon muscular and neural activity, may be mentioned as significant examples of the value of the conceptions of osmotic pressure and electrolytic dissociation in revealing the secrets of cell life. The most recent publications of the same investigator indicate that the domain of toxicology, with its poisons and anti-poisons, and even the "intermediate" bodies may be successfully invaded by the physical chemist.

From the various observations touched upon in what has preceded, three points seem especially worthy of emphasis:

1. The extraordinary variety and complexity of the chemical substances given off by the cells to the lymph and blood.

2. The chemical specialization of the various tissues of the body; and,

3. The value of chemical and physical conceptions as working hypotheses in the interpretation of life phenomena.

When we regard the blood serum in the light of these newer studies; when we think of the host of substances derived from the food on their way to hydrolysis or oxidation on the one hand, or to a larger synthesis on the other; when we recall the enormous number of receptors, immune bodies and intermediate bodies, complements and anti-complements, ferments and anti-ferments, coagulins, etc., which the blood of every higher animal must contain; when we think of the constancy of osmotic pressure retained despite the presence of a variety of dissociable salts in solution, we are led to exclaim with greater meaning than even Mephistopheles could have attached to the words: "Verily 'Blut ist ein ganz besonderer Saft!'"

The conception of a chemical differentiation of the tissues more divergent even than that which characterizes their morphology promises to be most heuristic.<sup>3</sup> Even though Ehrlich's hypothesis should later prove to be insufficient, and considering the present crude state of our chemical knowledge of the body, there can be but little doubt that it must be replaced or at least supplemented later by still more far-reaching speculations; it is at the present time stimulating a whole series of investigators to fruitful original research, and no more can be asked of any hypothesis. As long as it continues to lead to discoveries of importance, we may cling to it and utilize it. Only when it ceases to exercise a heuristic influence need we cast it aside for another more potent. Certain it is that aside from the chemical and physical peculiarities common to protoplasm in general, there are a host of special activities localized in the cells of different regions of the organism, the necessary consequence of ontogenetic development and a long phylogenetic history.

One can not help but be impressed with the fact that the important discoveries are being made by men who, no matter what their ultimate beliefs, in their work

avoid animistic hypotheses and animistic phraseology, and with René Descartes, choose the guiding hypothesis that vital phenomena are resolvable on analysis into the same elements as those underlying all other phenomena of the physical world. The mysteries of matter, energy and ether may never be fully explained to us, or they may ultimately be satisfactorily interpreted in terms of some grand monistic hypothesis. For the present this matters but little to us. It is enough that mechanistic conceptions are leading to discoveries of the greatest value for the alleviation of the sufferings and increasing the joys of mankind.

We have good reason to be proud of the progress already made in the unveiling of both the general and special processes which go on in the cell. Let us hope that in the near future, the investigators already at work, together with new men and new methods, may tear away more of the coverings which prevent our clearer insight; it is not, I believe, too much to hope that the present generation will be permitted to view with considerable distinctness many of the subtle processes which go on in the cell but which as yet we only dimly and vaguely begin to perceive.

## Clinical Report.

### GASTRO-JEJUNOSTOMY FOR STENOSIS OF PYLORUS—POSTMORTEM SIX YEARS LATER.

A. H. CORDIER, M.D.

Professor of Abdominal Surgery, University Medical College; Ex-President Mississippi Valley Medical Association; KANSAS CITY, MO.

Mr. C., aged 38, eighteen years ago began having digestive trouble. It was noticed at that time that solid particles of food in the stomach gave rise to more or less pain. A year or so later, vomiting began as a symptom. This vomiting was usually produced by the presence of food in the stomach. After the stomach was emptied the pain would cease, and the patient would be fairly comfortable until after another meal. On one or two occasions he had quite a perceptible show of fresh blood in the vomited material. This condition of painful digestion continued up to the time of my first examination. In addition to the above history I learned from the patient that large quantities of material would be thrown up that had been retained in the stomach for two or three days. As much as twelve or fourteen pounds of strongly acid, offensive material would be thrown up from the stomach at one time. This usually brought some relief, but even when the stomach was emptied of its solid contents gaseous distention would go on producing great distress from the pressure of the enormously dilated stomach. Cardiac and pulmonary dyspnea was a very prominent symptom as a result of this pressure against the diaphragm.

He had lost very much in weight at the time I saw him, and weighed only 115 pounds, was taking 20 grains of morphin a day, and was in a desperate condition in every sense of the word. My examination revealed an enormously dilated stomach and a very much emaciated patient. There was no tenderness on pressure at any spot over the abdomen; no enlargement or induration could be detected through the thinned abdominal walls. A diagnosis of pyloric obstruction resulting from the healing of a non-malignant ulcer was made. An operation having in view the establishing of a free communication between the stomach and the lower alimentary tract was advised and accepted.

It was noticed in the examination that the pylorus was very low and unusually far to the right of the median line. From this reason, at the time of the operation, the incision was made in the right semilunaris, believing that it would give the near-

3. Bichat, the founder of the science of histology, differentiated the tissues from one another chiefly by means of chemical reagents. He used the microscope only to a slight extent, and found it of but little use in his researches. Since his time, histologists supplied with a perfected instrument, have enthusiastically prosecuted microscopic research, very often, it is to be feared, to the neglect of chemical histological methods. Both morphological and chemical methods are of value to the histologist; they are reciprocally helpful. If morphologists would pay more regard to the methods of the chemists and chemists would take the trouble to more carefully enter into the thought of the morphologists, we should have better balanced views of histology and cytology than some of those which confront us in current text-books and periodicals.

est approach to the most dependent portion of the dilated organ. The correctness of this decision was verified at the operation. I found on opening the abdomen the stomach very much dilated, but in position as before described. Believing, as I do, that all of these operations should be primarily drainage procedures, the anastomosis was made nearer the pyloric end of the stomach than that usually advised or found necessary. The incision in the stomach was made in its anterior wall about four inches from the pylorus. A coil of the jejunum 15 or 18 inches below the pylorus was selected as the suitable site for the incision in this portion of the canal. The usual precautions were used in the application of the sutures in the use of the Murphy button.

The operation was quickly performed and the patient returned to bed in good condition. Following the operation there was no unpleasant symptom. In a few days he was able to take the necessary nourishment without any inconvenience or pain following its ingestion. The morphin was withdrawn from him, and at the end of three weeks he was not only broken of his morphin habit, but was able to return to his home, taking both liquid and solid nourishment with perfect comfort. He continued to improve until his former good

valvular action that prevented the contents of the stomach from going into the upper coil of the bowel. A similar arrangement seemed to exist preventing the bile from going into the stomach. On filling the stomach with air or water not one drop or bubble could be forced through the pylorus. The water would enter the lower segment of the bowel with perfect ease, and none at all would go into the upper segment until after the stomach and lower segment of the bowel were thoroughly distended.

As remarkable as it might seem, the Murphy button, instead of passing into the intestine and finding its way out into the external world, as is usual, had dropped into the stomach and remained there for nearly seven years, or until the time of his death. Its presence in the stomach had never given rise to a single symptom. One end of the button was very much destroyed, presumably by the secretions of the stomach.

The accompanying illustrations show very distinctly the strictured condition of the pylorus, also the perfect anastomosis between the bowel and the stomach. It also shows the distended condition of the stomach and the lower segment of the bowel with very little distention of that portion of the intestine above the site of the anastomosis.

Gastrojejunostomy (Murphy button). Patient died of pneumonia seven years later. Stomach is filled with air in this picture. Notice difference in size of distal and proximal ends of bowel; very little air in duodenal end.

health and weight were regained. He increased in weight until he weighed 180 pounds, and was strong and able to do any work that was necessary for him to do. His digestion was perfect and free from pain; the gaseous distention disappeared and the stomach seemingly regained its natural size and tonicity. He continued in this state of health for six and one-half years. He was then taken with acute pneumonia, and within two weeks died as a result of this attack.

I was fortunate in being able to make a postmortem in this case. On examining the stomach I found that there was a complete obstruction of the pylorus; that the stomach had regained its former size; that its muscles were well developed and in a healthy condition; that the portion of the duodenum and jejunum above the point of anastomosis, while in a healthy condition, showed well-marked evidence of atrophy from disuse. At the site of the anastomosis there was absolutely no omental or other adhesions except those made by the union of the bowel to the stomach. The opening from the stomach into the lower segment of the bowel was as large seemingly as at the time of the operation. There appeared to be a species of

Gastrojejunostomy (Murphy button) nearly seven years ago. Stomach removed from patient dead of pneumonia.

While the dropping back of the button into the stomach might be used by some as an argument against its use, this objection would certainly lose its force from the fact that not a symptom was produced by its presence, and also from the fact that the time of performing the operation is very much shortened, a no small item in many of these cases. The greatest of all in favor of the button is the fact that nearly every one of these cases recover from the operation if the work is properly done.

"Interviewitis" is a word nearly as good and entirely as bad as many that have been recently coined, and it is surely on a par with the thing it is designed to name. Almost every week one sees reports of interviews in the daily papers, all properly earmarked, none ever disavowed, in which it is plain that the doctor has been only too eager to be quoted. The interview is usually upon a matter about which the physician named has little knowledge and no special qualification for instructing the lay public whatever. His opinions are therefore without weight, and are almost always absurdly trite or erroneous.—*Amer. Med.*

## The Organization of the Medical Profession.

(Continued from page 515.)

### VIII.

#### MEMBERSHIP IN THE COUNTY TO CARRY WITH IT MEMBERSHIP IN THE STATE SOCIETY.

One of the most important resolutions regarding reorganization adopted by the American Medical Association last June was the following: "That membership in the county or district societies shall constitute membership in the respective state society without further dues, and that no one be admitted to membership in the state society except through county or regular district societies."

#### Essential to Representation.

Last week we called attention to the benefits to be derived by separating the business or legislative from the scientific functions of the state society, and suggested the necessity of recognizing that the county or district societies must create the business body. While it is not necessary to adopt the principle enunciated in the above resolution to carry into effect this idea, it is necessary that the bodies which create the business part of the state society be definitely recognized as branches of the state society.

When the American Medical Association changed its organic law, it took from the district, county and local societies the right of direct representation in its legislative body, limiting this right to the state and territorial societies. In doing so there was no thought of depriving the members of these subordinate bodies of the privilege of expressing their views, and of registering their desires, as regards matters of national importance, such as will be brought before the House of Delegates of the American Medical Association, but rather to create a way in which they could do this much better and more satisfactorily than under the old method. Instead of every subordinate society, large or small, in every part of the country, sending its representatives to the National body, thus making the latter unwieldy, it is proposed that such representatives shall first gather together as a state organization and then elect from among themselves one or more delegates to represent them in the House of Delegates of the American Medical Association. If the state society does not take in county or district societies, members of the latter who are not members of the state society will not be represented. The American Medical Association is therefore justified in asking each state society which has not heretofore done so, to arrange to give its subordinate bodies the right of indirect representation in the legislative body of the National Association, since the right of direct representation has been taken away in the interest of the greatest good to the largest number.

#### An Aid to Local Societies.

The comparative slight interest in state societies is partially due to the fact that they are separated from the local organizations. To the great majority of physicians a state society is a sort of superfluous body membership in which carries little distinction and no appreciable advantage, meeting once in a year and dormant the rest of the time. They have done nothing to make

the mass of practitioners think otherwise since they have no fraternal feeling or direct affiliation with them. The annual meeting of the average state society, the country doctor is apt to say, owes its general interest, aside from a very moderate social element, to the addresses and communications of specialists from the medical centers who thus utilize it for their coming in contact with their clientele of rural consultants. Not seldom this feeling is founded on fairly good reason. Direct affiliation with local societies will remove this sentiment. A state society should be a state society in fact as well as in name, not an oligarchy above and beyond the great body of practitioners. Its aim should be to build up strong local societies, and through them reach the members of the profession. One of the most important results to be gained from the plan suggested will be the building up of such live county societies. As has been mentioned many times, but it will bear repetition—the great, the all-important object now before us is the encouraging of county, or in thinly settled territory, district societies, so that every member of our profession may have the opportunity of society fellowship. The best way to build up these bodies is to make it impossible to obtain membership in the state or national associations, except through membership in one's own county society.

#### The Scientific Branch of the State Society Should Be Open to All.

The object of the scientific branch of the state society is the diffusion of medical knowledge. The primary object of its annual gathering is educational; the second is social and fraternal. There is no reason why every reputable physician should not be welcome to such a meeting, especially if he is considered by his fellow practitioners, who know him best, to be a desirable member of their society. There can be none unless the members of the state society desire that body to be select and exclusive, an idea which is as far from their wishes as it would be repugnant were it a fact. To make high professional attainments a qualification for membership in certain exclusive societies devoted to special work may be right, but it certainly would not be right in a body which claims to be democratic and representative, as all state societies are supposed to be. They all gladly welcome to membership every reputable physician, so that there can be no objection to absorbing all members of recognized county societies on this score. As far as excluding from the state societies those who are not reputable and ethical, it would seem that limiting membership to those who belong to county societies is more likely to prevent admission of such men than the present method of governing entrance. If, however, the subordinate societies are made, *de facto*, branches of the state society, then the latter can control admission of members to its branches by any rules it may deem best to lay down.

#### Would Result in Increase in Membership of the State Societies.

Membership in the state society would be greatly increased by adopting the county society plan. As an illustration, the membership of the Illinois State Society is 1170, according to the *Illinois Medical Journal*, and the membership of the subordinate societies is 3700. How many of the latter belong to the former we do not

know; but probably it would be under- rather than over-estimating, to say that 300 belong to the state society who do not belong to any subordinate body. Combining the county societies with the State would then give the Illinois State Medical Society 4000 members at once without any effort whatever. The combining of the subordinate bodies with the state society in Ohio would give about the same number. In many other states likewise large increase of membership in the state society will result when the plan recommended is adopted by them.

#### **Advantages from Increased Membership in State Societies.**

The advantages to be derived from this large membership in the state society are so many and so obvious that it will be unnecessary to more than hint at two or three. The most important of these will be an increased total revenue, at a small cost to the individual. The lack of money in the past has prevented the undertaking of many important measures. Little can be accomplished in this world without money and yet this fact does not seem to have been appreciated by the members of our medical societies. To illustrate this point of increased revenue, we again refer to the two states mentioned. The present membership of the Illinois State Medical Society should result in an income of \$3510, providing all pay their dues. Under the new order, the same annual assessment, \$3, would give an income of \$12,000, much more than would be necessary after the first year or two. Thus the annual dues could be reduced. The present membership—960—and annual dues—\$2—of the Ohio State Medical Society should net that body \$1920. If it adopts the broader scope and plan, the annual income on the same individual dues would be \$8000.

#### **Decreased Proportionate Expense.**

The larger the membership, the smaller is the proportionate expense. The financial outlay of the state society, of course, varies with the work done. It will not be an unfair statement to make that at least three-fourths of them have been doing nothing in the past except to hold an annual meeting, principally devoted to scientific work, and hence the only expense has been that which was connected with these annual meetings, that is, the secretary's salary, the printing and issuing of programs and transactions. The former varies from nothing up to two or three hundred dollars. The increase in membership would increase the work of the secretary, but not proportionately. The printing and sending out of the programs is a small item to be sure, but this would be increased but slightly with the increased membership. The publication of the annual transactions is always the greatest item of expense. It is well known that the greatest expense of producing a book is that which pertains to the first copy. The typesetting, putting the matter in the forms, the "make-ready" and getting the presses started constitute the greatest outlay. When the presses are running, the additional thousand or ten thousand copies adds very little to the cost of the press work. The plain white paper is a small item for each book, and the larger the number of copies the less the proportionate cost of binding.

If the annual volume of transactions could be sub-

stituted by a monthly journal—a most excellent thing to do for many reasons<sup>1</sup>—the reduction in cost to each individual by an enlarged circulation would be very great. Referring again to Illinois, the *Illinois Medical Journal*, owned and published by the State Society, would almost quadruple its circulation. The cost of getting out 4000 copies of that journal would be little more than that of 1000 copies, the added expense being simply the added cost of the white paper, an infinitesimal item for extra press-work and mailing. The good resulting through reaching the increased number at but a slight increase in expense, both as this applies to the annual transactions in book form and in a monthly journal, would be very great, without mentioning the very important fact that as regards the journal proposition as an advertising medium it would be a producer rather than a user of funds.

It will be urged that we are taking it for granted that all who now belong to subordinate societies will willingly stay in these bodies and thus become members of the state societies and assume the financial responsibilities that such membership carries. We certainly are taking this for granted, because we recognize as a fact that physicians are endowed with business sense, in spite of the statement so often made to the contrary. All will willingly give one, two, three or even five dollars annually for the privilege of being a member of the regular organization, provided they get value received for their investment. As business methods are expected to be adopted in the management of the regular organization when this is once effected, and as decided benefits of a practical nature will result from membership, there will be no hesitancy on the part of members of regular societies in paying the small annual assessments that will be required. Of course, if no greater advantage follows membership in the state society in the future than has followed it in the past there will probably be a large proportion who will object to this enforced membership. For, what has it been in the past? The average attendance at the majority of our state society meetings is less than one-third of the total membership. What advantage accrues to the two-thirds who do not attend—whether they can not or will not, does not matter—the annual meeting? What do they get for the \$2 to \$5 they pay each year? 1. A copy of the annual transactions which contain papers that, if they are of value, are published in the medical journals, a book that is usually thrown on one side and soon covered with dust, for the reason that it is of little interest except to those whose papers or discussions appear in its pages. 2. A satisfaction that one is helping in a good cause, and 3, the honor of being a member. The two latter reasons can not be considered from a business point of view. To secure membership in a medical organization, value received should be given for the annual dues. Physicians are business men, in some things at least. It is not necessary at this time to refer to what shall constitute value received; we are taking it for granted that, when thoroughly reorganized we shall enter on a new era in medical society management in which business methods will be adopted.

(To be continued.)

1. The journal would increase the membership of the local societies, and their additional income in time could be made to meet the expenses of the state body, that is if common business sense is employed. The average physician is far more ready to join a society if his membership includes the subscription to a live medical journal giving especial attention to the local medical interests of his commonwealth.

## HELMHOLTZ AND THE PUBLIC LECTURE PLATFORM.

Of the many phases that the life of Helmholtz presents to the student of his life and times, by no means the least important is the scientist as an exponent, in popular fashion, of the more difficult subjects of his investigations. These run all along the line of physics and physiology and include such subjects as painting, musical tones, as well as others more closely related to medicine. Too little stress is generally laid upon the great teacher's ability as a public speaker. His addresses and popular lectures form no mean part of the legacy that has come down to us from him—commending themselves as examples of what such expositions should be—dignified, interesting, instructive and inspiring. An untiring and successful teacher himself, he possessed well-defined ideas of the requirements of professional fitness and these he set forth in his Rectorial Address at Berlin University. A few of the axioms he laid down on that occasion are: "He who wishes to inspire his audience with a complete conviction of the truth of what he advances, ought, above all, to know from personal experience what produces conviction. It is necessary, then, that he should have known how to advance alone into a region where no one has ever broken ground; in other words, he must have worked upon the frontiers of human science and conquered for himself new domains. A master who presents only results acquired by others, suffices for scholars to whom authority is given as the source of their science, but not for those who desire to deepen their convictions to their final foundations." Of the judgment formed by students of their teachers he further remarks that the general current of opinion can not long be at fault. The majority among them come to us "with a reason sufficiently formed by logic, with a sufficient habit of intellectual effort, with a judgment so considerably developed by a knowledge of the best models, as to be able to discern the truth from the phraseology which has only the appearance of truth." The fitness for a teaching career, according to Helmholtz, is most surely marked by doing something for the progress of science, and in this connection he makes a claim that will surely be allowed by every one who has been a teacher or student, that a good lecture or demonstration demands from the listener much less sustained effort than a bad one; it enables the subject to be comprehended much more surely and much more completely, and with a well-ordered arrangement, bringing into

strong relief the principal points and the divisions, so that much more can be overtaken in the same space of time.

The main reason why Helmholtz gave the time and labor needed for the preparation of his popular lectures is he believed that the great body of scientific teachers and investigators owe something to the public and that the interests of the whole community are best served by properly directed extra collegiate teaching. It is not so much the *little* knowledge that is the dangerous thing as the *quality* of that knowledge. The laity will have, and always do manage to possess, medical information of a kind—if not the right kind so much the worse for scientific medicine. Movements to present popular courses of medical lectures have usually failed, chiefly because the initiative was not taken in the proper quarter.

Why should not the local medical societies, general and special, appoint a joint committee for the purpose of choosing from among their members lecturers of acknowledged ability to meet the demand for popular expositions of the truths of physiology and pathology and not leave these to furnish doubtful "copy" for the Sunday newspaper or the illustrated columns of the advertising charlatan? In the past, very successful and most interesting lectures on medical subjects have been given in the old Manchester "Science Series," as a part of the New York "State Science Lectures," in Chicago under the direction of a committee appointed by a daily newspaper, etc. Why should the medical profession delegate this function to irresponsible, even if perfectly sincere, laymen? It would seem as if we had pursued a dog-in-the-manger policy long enough. Surely the belief or suspicion that public lectures on medical topics are sometimes put to an unworthy use is no excuse for our neglect to provide them with proper safeguards against such a contingency. If the master who speaks of medicine as the "intellectual home in which he grew up" did not consider it improper or without his province to lay before a popular audience the fruits of his own and other scientific labors we can not be far astray in following his example.

## TYPHOID BACILLI IN THE BLOOD OF TYPHOID PATIENTS.

The examination of the blood of typhoid patients for the presence of typhoid bacilli at first gave exceedingly variable results, and there was a time when but little earnest work was done in this field. Of recent years, however, the systematic examination of the blood by cultural methods has been taken up anew by many investigators, and their results seem to have established definitely that the typhoid bacillus frequently exists in the blood in typhoid fever; indeed, it seems probable that it is present at some time in every case. The occurrence of typhoid bacilli in the rose-spots, in urine and in the various post-typhoid suppurative foci can be explained only upon the grounds that bacilli are carried

by the blood. Furthermore, the existence of clinical typhoid fever, without the existence of typhoid intestinal and other lesions, and due apparently to a pure typhoid septicemia, shows that typhoid bacilli may thrive well enough in the blood during life.

In this country bacteriologic examination of the blood in typhoid fever has been carried out more or less systematically by Cole in the Johns Hopkins Hospital<sup>1</sup> and by others. Cole obtained cultures of typhoid bacilli in eleven of fifteen cases, and in the last seven cases, in which the blood was diluted with from 75 to 150 parts of bouillon, bacilli developed in every experiment. The earliest period at which he obtained bacilli from the blood was on the sixth day; in several cases the bacillus was demonstrated in pure culture before the serum gave the agglutinating reaction. These observations are confirmed in every way by Courmont<sup>2</sup> of Lyons, who was led to seek the bacillus systematically in the blood of his typhoid patients in order to determine the value of the procedure in the prompt and early diagnosis of the disease. He obtained the blood by puncture of a vein at the elbow, and inoculated immediately into broth, using a small but varying quantity of blood and a large quantity of broth (3 c.c. of blood to 500 c.c. of broth being the usual dilution). If the flask appeared clear the following day, it was agitated thoroughly. He examined in this manner nine cases, in all of which he found typical bacilli in pure culture in the blood without a single failure before the twenty-third day. Hence he considers it probable that the bacillus occurs in the blood of all typhoid patients. He found it present as early as the fifth day, and while it seems generally to disappear towards the end of the third week it may occur in the blood at a much later period in prolonged cases and those with relapse. As far as Courmont's observations go, the bacillus presents the usual characteristics when it is isolated from the blood; usually it is of high virulence. At first the bacilli seemed less agglutinable than the laboratory stock cultures, but with time the agglutinability increased materially. In four cases typhoid bacilli were present in the blood at a period when the serum of the patient had absolutely no agglutinating powers, and for this reason Courmont advances the claim that the bacteriologic examination of the blood in typhoid fever is of decided value in the early diagnosis of the disease, especially when the serum reaction is absent.

The essential point in the technic of this examination is the use of considerable quantities of blood, relatively speaking, diluted in large quantities of broth. This makes the method somewhat complicated, and there is required the apparatus and facilities of a well-equipped laboratory. Because the bacilli in the blood are few it is necessary to use comparatively large quantities of blood, and in order to overcome the bactericidal action of the blood it is necessary to dilute the blood at least a hun-

dred times with broth. Further studies are necessary to work out many interesting details that suggest themselves as one reviews the work of Cole, Courmont and others.

#### ABSTRACTS, A VALUABLE FEATURE.

A short time ago one of our contemporaries indulged in an editorial expression of opinion that was decidedly unfavorable to the plan adopted by this journal and by several others, of giving a brief résumé of the leading articles in the current medical literature. It charged that the abstracts were incomplete, superficial, generally unscholarly and uncritical, and it mentioned without specifications a flagrant case in which the author's meaning was wholly misinterpreted. Undoubtedly such things occur, but they also are observed in critical résumés such as are found, say in our critical contemporary. Indeed, medical literature abounds in recriminations caused by such mistakes, which are sometimes unavoidable. Abstracts should not be critical; it is the policy of THE JOURNAL to avoid this, as it is deemed better to give so far as is possible a perfectly unbiased statement of the author's ideas. It is a harsh accusation, however, to say that those appearing in four of the eight medical weeklies of the country are "generally unscholarly" and one that ought not to be made by anyone so open to the criticism of ignorance of foreign medical literature as apparently is the writer of the editorial in question. One ought to be quite invulnerable himself to make such a sweeping charge against the scholarship of others.

The prophecy that the "abstract idea" is doomed to ultimate failure is, we believe, as incorrect as the assertion that it was new in weekly journals. The *Philadelphia Medical Journal*, which our contemporary credits with its origination, politely corrects this error, admitting that it derived the idea from one of the great German weeklies,<sup>1</sup> and with this, also the inference that it was about to discontinue its usual method of abstracting. This plan has found favor abroad, not only in the German weekly referred to but in other special and general publications and its use is extending. The numerous appreciative letters received from prominent medical men in this country convince us that it is not unfavorably considered here.

Critical summaries of special medical subjects of importance are excellent things if judiciously made, but they are often open to the same objections as to their incompleteness made against the abstracts, and are open to the further objection that they are not always unbiased statements of the views of the writers but are colored and we could sometimes say even adulterated, by the reviewer's prepossessions. The one can not supply the place of the other, useful as it may be, and with what experience we have had in working up medical literature, we would as a rule prefer—lacking original authorities—to depend upon the average abstract rather

1. Bulletin Johns Hopkins Hospital, 1901, July, xli, pp. 203-206.

than on "reports of progress," "critical summaries," etc., excellent as they are in their own way. We might say more on the subject, but this is probably sufficient. We trust that our esteemed contemporary will in the future be less sweeping and more judicious in its criticisms. If it lacked the enterprise to install such a feature in its own columns, this fact gives it no right to disparage the work of others.

#### LESSONS FROM TYPHOID EPIDEMICS.

It is perhaps unnecessary to call attention to the manner of origin of epidemics of typhoid fever; the subject may be regarded as somewhat trite. Yet the story of every epidemic, be it great or small, is worthy of attention, as it serves to fix more firmly in the mind of the physician and through him the mind of the laity the great importance of prophylaxis and of proper sanitary precautions. Two very instructive reports on small epidemics of typhoid fever have just been published. In last week's issue of *THE JOURNAL*,<sup>1</sup> Harri-man describes how 65 cases developed in a school where the general environment, the sewers and sewage disposal and the water supply were found perfect. But about September 15 a new milkman began to supply some of the milk and on October 8 three cases of the fever developed and others continued to do so until eighteen days after this milk supply was discontinued. There had been a case of typhoid fever in the milkman's family a few months before. On investigation it was found that this particular milkman rinsed his cans with water from two wells, one of which, the shallower, contained a large amount of organic matter with a large number of germs, among them one regarded as the bacillus typhosus. The cans were not scalded. The milk from this particular supply was served chiefly to students sitting at certain tables. Most of the cases were among these students. Sixteen young men in training for football drank daily double portions; of these sixteen, thirteen contracted typhoid.

The other report is by Rachford.<sup>2</sup> At a summer resort in northern Michigan 35 cases appeared among those who took their meals at a certain dining-hall. The local physicians with some of the physicians sum-mering there, with the cordial coöperation of the land-lady, formed themselves into a committee of investigation and made a formal search for the source of infection. The general water supply of the town, the milk supply, the water of the bay in which the resorters bathed, were all excluded by a careful study of the facts surrounding each individual case and the cases collectively, and then a search was made for the source of local contamination of the water or food supply. It was found that a manhole receiving the sewage and kitchen water from the dining-hall was distant but a few feet from two water tanks, in one of which vegetables and

fruit were placed for cooling, and in the other, water for drinking purposes was collected. The manhole was of brick and not cemented, the water tank of wood. On pumping out the latter, water from the manhole was seen to ooze through the intervening six feet of soil. The defects were corrected and the epidemic ceased abruptly after nineteen days. The original case of typhoid was believed to have been one which occurred in the building several months before.

It is worthy of note that in both these epidemics the diagnosis of the disease, the detection of the source of the infection, and the application of the remedy were effected without dependence upon the services of expert bacteriologists or chemists, though in each instance confirmatory aid was obtained from experts in these lines. We mention these facts not to decry the value of these aids, nor to advocate the attempt to get along without them, but to show that the practitioner and the country doctor who may be far removed from city laboratories, may often by a careful investigation of an epidemic of this sort and by a close analysis of his cases reach an almost certain conclusion as to the origin of the trouble and suggest the proper remedy. His knowledge of the broad principles of bacteriology and infections will often serve him, though he may be unable to understand the details or practice the technique of bacteriology.

#### DANGER OF UNPROTECTED FIREPLACES.

The British Home Secretary has published the statistics of child mortality from fire as given by 200 coroners in England and Wales for the years 1899 and 1900. From these it appears that there have been 1684 in-quests of children thus sacrificed, and in 1425 of these the evidence showed that an unprotected fireplace was the cause. The use of open grates is almost universal in Great Britain and this appears to be one of the prices they pay for it. The associations with it are generally considered the most cheerful, and an open fire figures largely in the description of English home life in literature, but such a holocaust as the above figures indicate reminds one of the Druidical sacrifices of early Britain and is anything but cheerful to contemplate. Undoubtedly the conservatism that is characteristic of our trans-atlantic relatives will keep it up, to some extent, even after this revelation. Taken altogether, with its good and bad qualities, the American stove has its advantages in safety as well as efficiency over the open grate.

#### QUACK METHODS IN HIGH PLACES.

Disreputable or questionable advertising methods are not restricted to any country, and we are probably as well off in this respect as are the transatlantic regions. At least we have no one here as prominent in surgery as a certain French operator whose alleged performances in connection with the Dreyfus trial, and certain still more recent events have excited not merely professional but also lay comment. Among the press dispatches from Paris we find the following: "Dr. Doyen's methods of advertising himself in connection

1. *JOUR. A. M. A.*, Feb. 22, 1902, p. 509.

2. B. K. Rachford: Study of a Typhoid Fever Epidemic, *Medicine*, December, 1901.

with the operation of separating Radica and Dodica, the Hindoo twins, are exciting general disgust among Paris medical practitioners. M. Charles Laurent, in the *Matin*, has belled the cat by denouncing the quackery of France's foremost surgeon in indignant terms. Dr. Doyen, in the meantime, issues daily bulletins wherein he does not scruple to advertise patent nutriments supplied to the patients." When this sort of thing becomes of such public interest as to be mentioned in cable dispatches, the notoriety becomes hardly desirable, however profitable it may be in some ways. An international reputation of this particular kind would seem least of all to be sought for. But tastes differ.

#### RESPIRATORY EXCHANGES IN TUBERCULOSIS.

Robin's claim that the respiratory exchanges in phthisis are exaggerated and that such excess in the non-tuberculous indicated a favorable soil for the disease, while the reverse conditions exist in arthritis, is already known to physicians. The importance of these facts, if they are such, seems hardly to have been duly appreciated, partly perhaps because, as stated by Robin, they emphasize the importance of heredity and predisposition. According to him, this exaggerated respiratory exchange is especially notable in the descendants of consumptives as well as in the victims of the disease themselves, though it may also be acquired by others through overwork, alcoholism, etc. In a recent session of the Paris Academy of Medicine<sup>1</sup> he again called attention to these facts and to certain deductions from the same, especially the facilities afforded for early diagnosis, the possibility of recognizing predisposition, and the new direction given to prophylaxis by suggesting the use of agents capable of retarding or restraining the organic tendency to retain too much oxygen and produce too much carbonic acid. Among these last he includes rest, especially in the reclining or recumbent position, and also certain medicinal agents such as cod-liver oil (ten ounces a day) tartar emetic in fractional doses, the arseniate and the cacodylate of soda. Temperature has also its effect; cold air diminishes production of carbonic acid; therefore, cold climates appear suited to the majority of consumptives provided injurious cutaneous exposure can be guarded against. The theory and its practical applications above suggested are apparently worthy of the attention of tuberculosis specialists, but so far we have seen very little published indicating that it has received their consideration.

#### SURGICAL TREATMENT OF MITRAL STENOSIS.

The operative treatment of wounds of the cardiac muscle is one of the latest advances in surgery. Enough has been done to show that in a certain proportion of cases—nearly 25 per cent, according to the latest statistics—life can be saved by prompt intervention and suture of cardiac wounds, at least in special cases, and the future of surgical intervention will probably give better results than in the past. Improved technique based upon widened experience can hardly fail to show improved results. That the success already attained has

been suggestive of still more daring operations in cases of cardiac abnormalities, is shown by a recent communication by Sir T. Lauder Brunton,<sup>1</sup> in which he discusses the feasibility of operation for the relief of mitral stenosis. Even a grave risk, he says, is perhaps justifiable for the chance of relieving the distressing symptoms that sometimes occur in this condition. Thus far his experimental work has been confined to the cadaver and to operations on healthy valves of cats, and very much more will be required to even make the operation a justifiable one. A needle wound of the ventricle, however, rarely gives rise to any hemorrhage and the knife need not be thicker than a needle, but in the auricle similar puncture may cause considerable bleeding. In experiments made for other purposes, Brunton says that he has often been surprised at the tolerance of the heart to manipulation, and it seems probable that this tolerance exists also in man. In operating, the knife should be introduced during systole as it is then less likely to wound the opposite ventricular wall. The pericardium should be opened, not only for the operation, but should be left open, to give exit to any oozing or hemorrhage, as the heart has little power to resist rapidly-occurring intrapericardial pressure. The paper is only a preliminary note and its suggestions are tentative merely, but it is noteworthy as indicating a trend of advanced surgical ideas. "The good results," he says, "that have been obtained by surgical treatment of wounds of the heart emboldens one to hope that before very long similar good results may be obtained in cases of mitral stenosis." The practical application of the suggestion is probably still only in the dim future if indeed it will ever be realized.

#### HYGIENE OF BARBER SHOPS.

The importance of hygienic measures in barber-shops has been emphasized anew in an article by Dyer<sup>2</sup> upon dandruff. Dermatologists agree that a large proportion of the cases of baldness is secondary to a seborrheic disease of the scalp. There is no certainty as to the essential cause of seborrhea, different investigators of the subject having described various micro-organisms in connection with it. The microbacillus of Unna and Sabouraud appear to be quite constantly present. Whether there is any particular bacterium which is alone responsible for the disease or not, it is generally conceded that it is probably parasitic in its direct origin. If this be accepted, then the liability of carrying the infection from one person to others by means of toilet articles is apparent. To prevent this hair-brushes, combs, etc., should not be used as common property for an entire household, nor for an entire community as is the custom in most barber-shops, but each individual should possess and use his own brush and comb. Such articles should be thoroughly cleansed occasionally, and in barber-shops should be frequently disinfected. Shaving instruments also are undoubtedly the means of spreading certain infections of the beard, especially tinea sycosis. It is not unlikely that other diseases of the skin due to micro-organisms may also be carried in the same manner. Under the conditions which prevail

1. The London Lancet, February 8.

2. Medical Review of Reviews, 1901, 1003.

1. Medical Press and Circular, January 29, p. 113.

in the ordinary barber-shop this is liable to occur at any time. Hyde goes so far as to say: "Where the whole or any part of the beard is to be removed every adult male should shave himself." Most of the dangers referred to could be eliminated if barbers would apply the principles of antiseptics and asepsis in their work. It would be no hardship to sterilize razors, strops, brushes, combs and hands. Little apparatus would be required and that used could be very simple and inexpensive. Efforts have been made in various places to compel barbers to employ antiseptic measures in their shops, but it is difficult to force such matters. If it becomes a matter of business and of pecuniary interest to the proprietor of a shop to manage his place upon proper antiseptic plans, something may be accomplished. Physicians could do much to bring about the desired reforms by requiring the shops which they patronize to carry out the measures indicated in a systematic and thorough manner, and by advising barbers as to the best and simplest means which are efficient in accomplishing the desired results.

#### ACUTE DYSENTERY IN THE UNITED STATES.

The influence of the Rockefeller Institute for Medical Research is beginning to make itself felt. Reports of work done under its auspices are being published, and a very interesting and valuable one is that by Vedder and Duval on the etiology of acute dysentery in the United States.<sup>1</sup> It will be recalled that Shiga in Japan isolated a bacillus from the discharges in acute tropical dysentery. Subsequently Flexner and Strong found the same bacillus in connection with dysentery in the Philippines, and Kruse in Germany. The bacillus is known as *Bacillus dysenteriae* (Shiga). The object of the work undertaken by Vedder and Duval was to show that the acute dysentery of this country is caused by the bacillus of Shiga. In order that a given bacillus may be regarded as identical with *Bacillus dysenteriae*, it must show, of course, the same cultural and morphological characteristics as standard cultures of the typical organisms, and it must give positive agglutination reactions with sera of known dysenteries. Vedder and Duval record three groups of cases of acute dysentery occurring, one in Philadelphia (five cases), another in an institution in Lancaster (three cases), and the other at the Springside Home, New Haven (fourteen cases). In all these cases typical bacilli like Shiga's bacillus were isolated from the feces according to recognized bacteriological methods. As practiced, the agglutination reactions were made with the patient's blood serum and cultures obtained by Shiga, Flexner and others, and also with bacilli, isolated by the authors, and the blood of the patients from which they were isolated as well as with other serums previously shown to agglutinate *Bacillus dysenteriae*. Finally they studied the agglutination produced by Shiga's antidysenteric serum. The general and unequivocal result of these studies is that acute dysentery in the United States is associated most closely with a bacillus indistinguishable from those obtained from epidemics in various parts of the world. The etiological relationship of *Bacillus dysenteriae* of Shiga to sporadic,

institutional and epidemic acute dysentery seems, therefore, to be well established. Physicians have good reason to feel happy over this demonstration; heretofore acute dysentery has been to a large extent an unsolved problem as regards the exact etiology, and the so-called institutional dysentery has been especially puzzling. While much work still remains to be done, particularly upon the mode of infection and upon the intelligent prevention of infection, it would seem that we have a most valuable diagnostic measure in the agglutination reaction, which seems to be fairly constant and definite.

### Medical News.

#### COLORADO.

**Fraudulent Diploma.**—Mrs. E. W. M. Cory, Denver, charged with obtaining a license to practice by false and forged evidence, has been found guilty. The complaint against "Dr." Cory set forth that she obtained a copy of a diploma from the University of Michigan by representing herself to be Dr. E. W. Moores, who graduated from that institution in 1884 and that her diploma had been destroyed by fire.

**Guardsmen Instructed in Military Medicine.**—The surgeon-general of the state, Dr. William W. Grant, Denver, has inaugurated a series of lectures on elementary subjects for the benefit of the National Guard. In his first lecture he quoted statistics to prove that the army surgeon should be a general practitioner rather than a surgeon. During the Spanish war 5000 men died from disease aside from wounds, while only 450 perished from gunshots. He discussed questions of personal cleanliness, the digestibility of foodstuffs, cooking and clothing.

**In Memoriam.**—The Denver and Arapahoe Medical Society held a meeting in memory of Drs. Clayton Parkhill and J. T. Eskridge, deceased members. The following program was carried out: Introductory remarks, Dr. Leonard Freeman, president; reports of resolutions committees, Drs. William C. Bane, and Josiah N. Hall; "J. T. Eskridge, the Public Spirited Citizen and Friend of the Court," Tyson Dines, of the Denver bar; "Clayton Parkhill, Citizen-Soldier," Brig. Gen. Irving Hale, U. S. V.; "Eskridge, Alienist, Neurologist, Scientist," Dr. Edward Jackson; "Parkhill, Surgeon and Anatomist," Dr. Josiah N. Hall; "Eskridge, His Extra Professional Character," Dr. William Munn, and "Parkhill, the Teacher of Medicine," Dr. Robert Levy.

#### CONNECTICUT.

**Hartford Hospital Fund.**—The fund for the aid of the Hartford Hospital now amounts to \$38,827, and \$5000 has been donated to the permanent fund.

**General Hospital Society.**—At the annual meeting of this body at New Haven, Drs. Francis Bacon, Charles A. Lindsley, William L. Bradley and William W. Hawkes, all of New Haven, were elected directors. The prudential committee reported that the patients treated in the past year had paid \$24,017, and that the receipts for the year amounted to \$57,863.

**Litchfield County Hospital,** Winchester, has been publicly dedicated. It has been erected at a cost of \$42,000, of which the state furnished \$30,000. The officers of the hospital are Dr. Edward H. Welch, president; Dr. Arthur L. Clark, vice-president; Dr. William S. Richards, secretary; and Drs. William S. Richards, Edward L. Pratt, Edward H. Welch and William S. Hulbert, visiting staff.

**State Mortality and Infectious Morbidity.**—The January deaths in the state were 1172, 127 more than for the preceding month and 267 less than for the corresponding month of 1901. The annual death-rate was 15.4 per 1000. Infectious diseases were reported as follows: Smallpox, 32 cases; measles, 115 cases; scarlet fever, 360 cases; cerebrospinal fever, 2 cases; diphtheria, 225 cases; pertussis, 69 cases; typhoid fever, 31 cases, and consumption, 25 cases.

**New Haven Hospital.**—At the annual meeting of the directors of this institution, the following staff was selected: Attending physicians, Drs. Samuel D. Gilbert, William G. Daggett, Louis S. De Forest, Charles J. Foote, Max Mailhouse and John S. Ely; attending surgeons, Drs. Francis Bacon, William H. Carmalt, Thomas H. Russell, William W. Hawkes and Leonard C. Sanford; consulting physicians and surgeons, Drs. Charles

1. Jour. of Exper. Med., Feb. 5, 1902, pp. 181-205.

A. Lindsley, Robert S. Ives, Frank E. Beckwith, Walter Judson, William L. Bradley and Timothy H. Bishop; laryngologist, Dr. Henry L. Swain; ophthalmologist, Dr. Henry W. Ring; chemist, Dr. Herbert E. Smith; pathologist, Dr. Charles J. Bartlett, and obstetrician, Dr. Otto G. Ramsay.

#### ILLINOIS.

**Incurable Insane.**—The 99 incurably insane patients assigned to the new hospital at Bartonville from the Illinois Eastern Hospital, Kankakee, were safely transferred, February 13.

**No Spitting in Decatur.**—Decatur passed an anti-expectoration ordinance, February 17, making it an offense punishable by a fine of from \$2 to \$5, to expectorate on any public sidewalk, doorstep or elevator.

**A hospital car** was attached to each of the five trains required to transport the Twenty-ninth Infantry from Fort Sheridan to the Presidio, en route to the Philippines. This was rendered necessary by the prevalence of measles at the post.

**Compulsory vaccination** has been ordered by the Chicago and Alton Railroad, under penalty of dismissal, and this mandate is said to take in president and office-boy. This road has also arranged to subject each passenger coach, at the end of each run, to thorough fumigation.

**Personal.**—Dr. Vincent J. Cohenour, Chicago, has located in Joliet.—Dr. Harry W. Giles, Wataga, has moved to Knoxville, and his brother, Dr. William N. Giles, Rio, succeeds him.—Dr. William R. Kincaid and family, of Elkhart, have moved to Denver, Colo.—Dr. Albert J. Maris, Oakland, has located in Waterloo, Ind.—Dr. W. P. Davidson, Laplace, is about to move to Lovington.—Dr. George E. Krieger, South Chicago, has been appointed surgeon of the Inland Steel Company, with headquarters at Indiana Harbor.—Dr. J. Harvey Banks, Atlanta, will locate in Lincoln.—Dr. Clyde F. Horner, El Paso, has moved to Knoxville.—Dr. Preston Kyes, Chicago, has been appointed a Fellow in the Rockefeller Institute of Medical Research, and will leave for Europe April 1.—Dr. D. C. Strong, Chicago, has been appointed house physician of the Wichita (Kan.) Hospital.—Dr. Edgar L. Phillips, a retired physician of Galesburg, will move to Goshen, N. Y., his old home.—Dr. Frank G. Kuhls, Aviston, has moved to Breese.—Dr. John F. Tidwell, Crab Orchard, has moved to Marion.—Dr. E. R. Lovesee, Harvard, has located for practice in Monticello, Wis.

**Healers Lose.**—The Supreme Court has decided that magnetic healers and osteopaths must have a license to practice, in the case of the People against George P. Gordon, an advertising "healer" of Rockford. Gordon was charged with practicing medicine without a license, and after trial the Circuit Court directed the jury to find for the defendant. The Supreme Court reversed and remanded the cause. The following is the text of the finding of the court:

We all agree that the object of this [the statute] is to protect the sick and suffering and the community at large against the ignorant and unlearned who hold themselves possessed of peculiar skill in the treatment of disease, and to prevent them from holding themselves out to the world as physicians and surgeons without having acquired any knowledge whatever of the human system or of the disease and ailments to which it is subject. Without some knowledge of the location and offices of the various nerves, muscles, and joints the manipulation of those parts and the flexing of the limbs can not be intelligently, if, indeed, safely, practiced.

Merely giving massage treatment or bathing a patient is different from advertising one's business or calling to be that of a doctor or physician, and, as such, to administer osteopathic treatment. The one probably falls within the profession of a trained nurse, while the other does not.

#### Chicago.

**Resignation Demanded.**—Warden Healy of the County Hospital has asked the resignation of Dr. Herbert R. Hammond, a member of the attending staff, because he allowed an interne under his personal supervision to perform an amputation. This action the warden construed as a violation of the rule prohibiting internes from performing operations in which an anesthetic is administered.

**Scarlet Fever.**—The Department of Health in contrasting the mortality from scarlet fever and smallpox during the past three years shows that the mortality from the first was 924, while smallpox claimed only 7 deaths. It expresses the hope that in the munificent foundation of the McCormick Memorial Institution for Infectious Diseases—in which this infection is the first to be studied—that a disease, often more merciful in the life it takes than in the crippled survivor it spares, may finally be shorn of its terrors.

**Cook County Clinical School.**—The incorporation of the Cook County Clinical School, Chicago, is reported from Springfield. The incorporators are said to be Daniel D. Healy, John J. Hanberg and William McLaren. The first of these was president of the Board of County Commissioners, and is now warden of the County Hospital, and the second is president of the County Board. This looks strange, coming so soon after Warden Healy's radical decisions regarding clinics at the hospital, rights of internes, discipline of attending staff, etc., but perhaps it is merely a coincident.

**Pneumonia, Influenza and Cancer Mortality.**—In the last dozen years influenza has become not only an important factor in the mortality of the city, but as a mischievous complication has notably increased the death-rate from pneumonia, the deaths from which have increased 50 per cent. since influenza appeared in 1889. Cancer is increasing with frightful rapidity. In the decade ended in 1870 there were only 7.3 cancer deaths in every 1000 deaths from all causes in Chicago. In the decade ended in 1900 there were 28.9 such deaths in every 1000—an increase in thirty years of more than 80 per cent. Last year there were 1003 deaths from this disease in a total of 24,406 deaths from all causes—a proportion of more than 41 in every 1000, instead of the 7.3 in the decade of 1870, of the 14.5 in that of 1880, of the 19.8 in that of 1890 and of the 28.9 in that of 1900.

#### INDIANA.

**Hospital for Garrett.**—A new hospital to cost between \$35,000 and \$50,000 is to be erected in Garrett. It will be called the Sacred Heart Hospital.

**Pledges for Methodist Hospital.**—The Methodist churches of Indianapolis, on February 16, raised \$30,000 in subscription for the \$200,000 hospital which it is proposed to build there.

**New College Building.**—Central College of Physicians and Surgeons, Indianapolis, has purchased a site on North Senate Avenue and will erect a new building for laboratories and recitation rooms thereon.

**Indiana Mortality for January.**—The reports to the State Board of Health show a decided improvement in the health of the state as compared with the preceding month, and as compared with January, 1901. The number of deaths reported was 2829, an annual rate 13.2 per 1000. In January, 1901, there were 3460 deaths, or 16.2 per 1000. The number of deaths from important causes were: Violence, 117; smallpox, 5; cancer, 83; puerperal fever, 12; diarrheal diseases, 20; whooping cough, 18; measles, 2; scarlet fever, 23, and diphtheria, 4.

#### KANSAS.

**Douglas County Medical Association,** of Lawrence, has been incorporated without capital stock.

**The new Post Hospital** at Fort Leavenworth has been inspected by a board consisting of Major Henry P. Birmingham, surgeon, U. S. A., and Lieut. Herbert M. Smith, assistant surgeon, U. S. A. The building is now practically complete and will be ready to receive patients early in the spring.

**Appeals Against Medical Law.**—Dr. M. W. Wilcox, of Barton County, recently fined \$50 for practicing medicine without a license, has appealed to the Supreme Court, the only question to be considered being the validity of the law passed by the last legislature requiring physicians to secure licenses before practicing in the state.

**Personal.**—Dr. Alfred C. Davis, Hamlin, has been appointed surgeon to the St. Joseph and Grand Island, and the Kansas City, Omaha, and Council Bluffs railways.—Dr. John W. Lauck, assistant surgeon at the National Military Home, Leavenworth, has resigned and will enter practice at El Reno, Okla.—Dr. H. H. McLellan, St. Mary's, has moved to Topeka.—Dr. Meigs F. Thomas has been appointed physician at the federal prison, Leavenworth, vice Dr. David M. Dill, deceased.

#### KENTUCKY.

**Non-Resident Physicians.**—The Kentucky State Board of Health notifies us that non-resident physicians can not be registered in the state.

**Dr. Rodman's Estate.**—The will of the late Dr. James Rodman, Hopkinsville, was probated February 23. The estate is valued at nearly \$100,000.

**Epileptic Colony.**—A bill has been introduced in the senate establishing an epileptic colony at Lakeland Asylum, and appropriating \$75,000 for the purpose named.

**Dr. John Mason Williams,** Louisville, who was sued for alleged malpractice, was given the verdict by the jury, Feb-

ruary 18, evidence showing that the plaintiff's condition was due to disobedience of the orders of his physician.

**Personal.**—Dr. Charles H. Voorhies, Jr., has been re-elected health officer of Lexington, and Dr. S. L. Holm, city physician. —Dr. James H. Souther, Three Forks, has moved to Alvaton. —Dr. W. O. Green has resigned as clinical lecturer on rectal diseases in the Kentucky School of Medicine, at Louisville. —Dr. Vernon Robins, city chemist and bacteriologist of Louisville, has fitted up a laboratory in the City Hall.

#### MAINE.

**Bowdoin Medical College** opened its spring session with a freshman class of 38.

**Hospital Association Meets.**—The General Hospital Association of Knox County, at its annual meeting, elected Dr. John M. Wakefield, Warren, president; Dr. Willis F. Hart, Camden, vice-president; Dr. Addison R. Smith, Rockland, secretary, and Dr. Walter M. Spear, Rockland, treasurer. The hospital will be ready for occupancy in April or early in May.

**Personal.**—Dr. J. M. Lowe, Vinalhaven has entered the Central General Marine Hospital, Lewiston, as an interne, to succeed Dr. D. A. Barret. —Dr. O. M. Head, North Chesterville, has associated himself with Dr. Benjamin F. Makepeace, of New Sharon, who, owing to spinal disease, has been obliged to confine his practice to office work. —Dr. James F. Hill, Waterville, has been appointed assistant surgeon National Guard of Maine and also examiner-in-chief of the Maine Grand Lodge A. O. U. W. —Drs. Alfred Mitchell, Jr., and Richard B. Small have been elected to the staff of the Maine General Hospital, Portland, as adjuncts in surgery. —Dr. W. L. Hayes, city physician of Gardiner, has resigned and located in Massachusetts.

#### MARYLAND.

**Phi Beta Pi Banquet.**—The members of the Phi Beta Pi fraternity of the College of Physicians and Surgeons, numbering about 40, held their banquet, February 18.

**Personal.**—Dr. John Arthur Luetscher, Baltimore, has been appointed lecturer on normal physical diagnosis in the Woman's Medical College. —Dr. R. K. Crothers, of Elkton, had a paralytic stroke, February 21.

**Maryland Woman's Quarter Club Sanatorium.**—Drs. William Osler, William H. Welch, L. McLane Tiffany, I. E. Atkinson, S. C. Chew and Robert Johnson have agreed to serve as a committee which will co-operate with the state authorities in procuring a suitable tract of land for the proposed new Maryland Woman's Quarter Club Sanatorium, and to serve as trustees of the fund therefor.

**The quarter centennial** of the Johns Hopkins University was celebrated with great pomp and ceremony on February 21 and 22. Thirty-three honorary degrees were conferred, among them LL.D. upon Dr. John S. Billings, of New York, and that of M.A. upon Drs. W. T. Councilman, of Harvard University, Henry M. Thomas, and Robert L. Randolph, of Baltimore. A luncheon and reception was held by the trustees of the medical school of the hospital on the afternoon of the second day. Private receptions were held by Drs. Osler, Welch, Paton, Earle, Gilman and others. Dr. Hurd, of the Johns Hopkins Hospital, entertained President Angell, of the University of Michigan, and Dr. John S. Billings, of New York, the designer of the hospital.

#### NEW MEXICO.

**Sanatorium at Silver City.**—The Sisters of Mercy have decided to build a large sanatorium in Silver City.

**Sanatorium for Raton.**—Eastern capitalists intend to build a sanatorium at Raton, to cost \$100,000 and to accommodate 150 patients.

**St. Joseph's Sanatorium,** Albuquerque, is almost completed and will be ready to receive patients early in April. The cost of the building will be about \$40,000.

**A solarium** is being built at the Government Sanatorium for Tuberculosis at Fort Bayard. During the last two years the government has expended about \$200,000 on this institution and has put in a new sewerage system, waterworks, etc.

#### NEW YORK.

**Olean General Hospital** directors have purchased a lot and building for \$6000 and will be given possession in May, when the building will be remodeled for hospital uses.

**Isolation Hospital Donated.**—Mr. Robert M. Bruce has donated a 15-acre plot of ground to the town of Greenwich and

will erect thereon a number of one-story buildings to be used as an isolation hospital.

**Through Regular Channels Only.**—The Commissioner of Charities and Corrections of Syracuse has notified the physicians of the city that the department will not pay for the hospital service rendered any patient (emergency cases excepted) unless he or she be committed by the department physician.

**Quinquennial Vaccination.**—A bill has been introduced in the senate by Dr. McCabe, of Brooklyn, which provides for free and compulsory vaccination of all inhabitants of the state who come under the control of boards of health. If passed, it means enforced vaccination once every five years.

#### Buffalo.

**Dr. John A. Fordyce,** New York, gave an address, illustrated by stereopticon of clinical and pathological cases in dermatology, before the Academy of Medicine. Preceding the meeting a dinner was given in his honor at the Saturn Club by Dr. Grover W. Wende.

**Swine and Smallpox.**—Dr. William G. Bissell and Charles H. Zink, D.V.S., have made the following preliminary report on the investigation of a peculiar dermal disturbance in swine and its possible relation to smallpox; based on the discovery of the existence of a disease of septicemic origin with papular and pustular appearances, resembling smallpox, in swine brought from a particular part of the country:

1. The unusual disease noticed in swine is not of the same nature as smallpox.
2. In the opinion of the investigators, it is impossible by any known means of inoculation, to communicate smallpox to swine.
3. There is an infectious agent present in vaccine that is distinct from that present in the virus of smallpox.
4. The peculiar dermal disturbance, as seen in the swine, is of unusual occurrence in this section of the country, and so far as it has been possible to ascertain, it is not described in the literature of the day.
5. Inoculation of swine with the virus of smallpox does not confer immunity to vaccinia.
6. Most of the reports of the transmission of smallpox to the lower animals are without scientific substantiation.
7. The investigators would suggest that with a more complete study into the nature of the variolæ of the different domesticated animals, a greater distinction, rather than a closer relationship, will be established, and that the relationship between these diseases and smallpox, with a possible few exceptions, will be found equally remote.

#### New York City.

**Dr. Beverly Robinson.**—As a token of esteem, physicians formerly connected with the staff of St. Luke's Hospital have presented to Dr. Robinson, one of the visiting physicians, a handsome silver cup.

**Hebrew Hospital in Brooklyn.**—A number of wealthy Hebrews of Brooklyn have taken the first steps toward the establishment in that borough of a Hebrew hospital. They have formed the Jewish Hospital Society, which has a membership of 600, and already \$25,000 has been pledged.

**Women and Physicians for School Inspectors.**—Of the 110 school inspectors appointed for the Borough of Manhattan by President Cantor, 44 are women and 22 physicians. Mr. Cantor believes that by placing two women and one physician on each of the local boards in the borough, the inspections will lead to much better practical results, and school life will be materially improved.

**An Immoral Healer.**—Dr. John Armstrong, formerly of Gloversville, N. Y., but now of Queens County, is under arrest on the complaint of a 15-year-old girl, who alleges that the medical treatment she was compelled to undergo by her mother at the hands of this practitioner was such as to be subversive of good morals. The mother and a number of fashionably gowned women appeared in court, in the double rôle of patients of Dr. Armstrong and as witnesses in his behalf. The description of the method of treatment employed by this healer was such as to lead the District Attorney to insist upon a most searching investigation. Incidentally, it may be mentioned that this "vital force healer," as he styles himself, made a pitiful appeal to the magistrate to allow him to replenish his stock of morphia, as he uses this drug to steady his nerves. He says the "vital force" is transmitted to his patients through his hands, but his healing power is "like many of the things in the Bible, indescribable." Judging from the comments made at the trial his therapeutic methods are likewise "indescribable," though he assured the court that "there was nothing immoral in his methods except in the eyes of the impure."

#### OHIO.

**The Cleveland Medical Journal Company** has been incorporated with a capital stock of \$6000.

**Gifts to Cleveland Hospitals.**—Mrs. Mary H. Castle, Cleveland, has given \$10,000 each to the Huron Street and Lakeside hospitals.

**Illegal Prescriber Fined.**—J. P. Berney, Cincinnati, a colored, unregistered practitioner pleaded guilty to illegal prescribing and was fined \$21 and costs.

**Fifty-Thousand-Dollar-Eye Suit Decided.**—Dr. Frank S. Wagenhals, Columbus, who was sued for \$50,000 by a convict whose mutilated eye he removed in order to save the other eye, has been vindicated by the court, which found in his favor.

**Sanatorium Burns.**—The Central Ohio Sanatorium at Fountain Park, recently purchased by Drs. George W. Pickering and Robert M. Henderson of Urbana and Dr. Clarence M. McLaughlin, Westville, and equipped by them, was burned, February 8. The patients were all rescued, but the building is a total loss.

**Letting Down the Bars.**—On account of the agitation engendered by the law requiring all applicants for license to practice medicine to pass an examination before the State Board, Representative Painter of Wood County has introduced a bill which provides that all Ohio medical students matriculating in any recognized medical college of the state on Jan. 1, 1902, or thereafter, may upon graduation begin the practice of their profession without taking the medical examination as given by the State Medical Board.

## PENNSYLVANIA.

### Philadelphia.

**The Resignation of Dr. D. D. Stewart** as professor of diseases of the stomach was recently accepted by the Board of Trustees of the Polyclinic Hospital. Dr. Joseph Sailer was elected to fill the vacancy.

**Weir Mitchell Honored.**—At the public exercises held by the University of Pennsylvania on Washington's birthday, Dr. S. Weir Mitchell read an original, scholarly finished and impassioned poem, and was one of several distinguished persons who received honorary degrees.

**Resignations from Orthopedic Hospital Staff.**—Dr. S. Weir Mitchell recently resigned as senior physician from the Orthopedic Hospital and Infirmary for Nervous Diseases. He had held the position for thirty years. Dr. John K. Mitchell was elected to fill the vacancy caused by his father's resignation. The resignation of Dr. J. Madison Taylor, as assistant physician, was also accepted. The elder Mitchell remains as consulting physician to the hospital.

**Roswell Park on Medieval University Work.**—Dr. Roswell Park, of Buffalo, N. Y., on February 19, delivered an address to the Medical Society and the medical students of the University of Pennsylvania, under the auspices of the Charles K. Mills Neurological Society. The address on "University Work in the Middle Ages" was a graphic portrayal of student life and of the overshadowing hand of the church in medieval times, and of the final emancipation of the practice of medicine from the domination of the church.

**Vaccination or Filth.**—Great interest in medicolegal circles was recently aroused by trial of a certain case in Common Pleas Court. Damage suit was brought by Mrs. Bridget Nugent against Dr. Harvey M. Richter to recover for the death of her 6-year-old child, which Dr. Richter had vaccinated. The attorney for plaintiff is an antivaccinationist, and persisted in displaying his theories, though the judge constantly ruled that the matter was irrelevant. Members of the Antivaccination Society were on the witness stand. Plaintiff alleged that Dr. Richter, in vaccinating her child, Sept. 11, 1900, used impure virus; that his method was careless; that, as a result, impetigo contagiosa developed, from which the child died October 20. Plaintiff further alleged that defendant did not exercise proper skill and diligence in the treatment of the latter disease. To the reputable doctors who heard the testimony, much of it by eminent physicians or experts, it seemed to be conclusively shown that Dr. Richter had used much more than ordinary care in the vaccination; that the impetigo, which did not develop for nearly a month after vaccination—the vaccination would have healed—could by no possibility have been introduced at the time of vaccination, the period of incubation of impetigo being a few days at most; furthermore, that defendant recognized the disease and gave eminently proper treatment, and that he exercised unusual diligence in the case. Contributory negligence on the part of the plaintiff seemed to be established by the testimony of several physicians, all of whom testified to the filthy hygienic conditions of plaintiff's home. As to the

latter, several witnesses for plaintiff were called who testified to the cleanliness of the surroundings. Referring to the conflicting testimony on this point the judge in his charge to the jury said:

It is for you to say which of the witnesses you will believe. It is for you to say whether it is probable that these physicians would come here and swear that a condition of filth existed when it did not exist. Is it likely that they would come here to do that? Have they any motive for coming here to tell you, in the presence of God, a lie like that? It seems to me that perjury exists somewhere in this case.

If you conscientiously come to the conclusion that the defendant was guilty of any negligence, or want of ordinary care and diligence, resulting in the injury to the plaintiff complained of, you will not hesitate to say so by your verdict. But if, on the contrary, you come to the conclusion that the plaintiff's complaint is altogether unfounded, then it concerns not only the interest of the parties in the present cause, and not only the interest of public justice, but also the established medical fame of this city, a fame established by many examples of men great and distinguished in this profession, who have lived and labored and died—that you put an end, so far as you can, to experiments by unjustifiable lawsuits against skilful, attentive and humane physicians.

The jury, after deliberating twenty hours, returned a verdict for the plaintiff, awarding her \$1000 damages. Many of the profession in the city are aroused and indignant at what they believe an unjust decision. Not only individual members but medical societies purpose taking a vigorous part in continuing the fight of the case in the courts.

## GENERAL.

**New Marine Hospitals.**—Bills establishing marine-hospitals at Pittsburg and Savannah were ordered favorably reported by the House Committee on Commerce at Washington, February 14.

**Smallpox.**—During January there were 11,015 cases of the disease in the United States, and 253 deaths, a death rate of 2.25 per cent., approximately.—The number of new cases in Philadelphia for the week ended February 22, namely, 63, was the smallest reported this year.—For the first two weeks of February there were reported to the New York Health Department 119 cases of smallpox and 24 deaths from this disease. The people are disposed to believe that "the chief horror of smallpox" is to be found in the compulsory removal from home and friends and isolation. This feeling has been voiced in the daily press in the popular demand for the building of a private smallpox hospital. Although the agitation is only a few days old there seems to be little difficulty in raising the necessary money. If the plan were to build a new pavilion to some existing hospital, such as the Minturn Hospital for contagious diseases, it could probably be carried out for \$50,000, but if a separate hospital is to be erected, the cost would easily be double this amount. It is stated that last year Mr. Carnegie offered to the managers of the Minturn Hospital \$50,000, but it was declined because of the difficulty experienced in finding a site for such a hospital in the Borough of Manhattan. A new center of infection has just been discovered in a densely populated quarter of Williamsburg, inhabited by negroes.—On February 17 the eleventh case of smallpox at Baltimore was sent to quarantine. It is supposed to have originated in contagion among the crew of a steamer from Liverpool, the captain of which mistook a case of smallpox for peritonitis. The twelfth case of smallpox developed February 21. The contagion was traced to Philadelphia.—Smallpox was reported in the following counties in Indiana during January: Shelby 9 cases, Dearborn 11, Union 2, Knox 12, Perry 12, Dekalb 1, Howard 1, Vanderburg 11, Marshall 7, Warrick 27, Morgan 23, Adams 3, Gibson 3, Marion 34, Greene 26, Montgomery 43, Wayne 8, Wells 6, Fountain 50, Grant 10, Owen 17, Wabash 12, Decatur 2, Daviess 15, Pike 7, Monroe 8, Vigo 2, Jefferson 17, Delaware 3, Spencer 60, Floyd 9, making a total of 461. Five deaths from the disease occurred.—In Michigan during the week ended February 1, the disease was reported at 139 places.—Dr. Frederick Dillingham, assistant sanitary inspector for Manhattan, furnishes the following comparative table of cases and deaths from the disease in January, 1901, and January, 1902:

| State.            | January, 1901. |         | January, 1902. |         |
|-------------------|----------------|---------|----------------|---------|
|                   | Cases.         | Deaths. | Cases.         | Deaths. |
| New York .....    | 82             | 11      | 295            | 25      |
| Pennsylvania..... | 20             | 1       | 581            | 81      |
| New Jersey .....  | 7              | 0       | 327            | 47      |
| Minnesota.....    | 425            | 3       | 1740           | 11      |
| Illinois .....    | 94             | 2       | 176            | 1       |
| Wisconsin .....   | 290            | 1       | 4357           | 23      |

Smallpox in modern times, says the Health Commissioner of Chicago, does not merit a title of the concern its appearance in a community always excites. A hundred years of vaccination has demonstrated that smallpox is one of the most easily controllable of diseases. The higher the degree of civilization

in a community or a country, as measured by its work in sanitation and preventive medicine, the less the importance of smallpox. In Chicago the deaths from the disease have steadily diminished from: 17.5 in every thousand deaths from all causes in the ten years between 1861 and 1870 to 4.9 in the ten years 1891-1900—a decrease of 71.5 per cent. from the earlier proportion. Smallpox is a vanishing disease. No one need—no one can—"catch" it except through a culpable, if not criminal, neglect of vaccination.

#### CANADA.

**Dr. George K. Grimmer** has been appointed assistant laryngologist to the Western Hospital, Montreal.

**McGill University.**—The total number of students attending classes at McGill reaches 1114, distributed as follows among the different faculties: Law, 60; medicine, 490; arts, 294; applied science, 254; veterinary science, 16.

**New Superintendent of the London Asylum.**—Dr. T. A. McCollum, of Dunnville, Ont., has been appointed to the superintendency of the London Asylum rendered vacant through the unfortunate death of Dr. Bucke. Dr. McCollum has been a leading surgeon of the Niagara Peninsula for the past twenty years.

**Toronto University Medical Building.**—The problem of how to solve the financial aspect of the new medical building for Toronto University has been solved by the adoption of the suggestion of the Minister of Education. The trustees of the University will advance the money upon which the medical faculty will pay 4 per cent. interest per annum. To this the government will give its approval.

**Low Birth-Rate in Ontario Cities.**—The total births recorded in Ontario in 1900 was 46,127, as compared with 44,705 in 1899. There has been an actual decrease in every city in the province excepting Ottawa, London, St. Catharines and Guelph. The birth-rate of 23.4 in 1891 has decreased by some 20 per cent. in the various cities of Ontario. Applications for insurance in 1862 showed 7.8 children per family, and in 1900 6.7, a decrease of 14 per cent.

**Death of Dr. R. M. Bucke.**—Dr. Richard Maurice Bucke, superintendent of the Asylum for Insane at London, Ont., a prominent alienist, and lifelong friend and literary executor of Walt Whitman, accidentally slipped on the ice on the veranda of his residence on the evening of February 20, instant death resulting. Dr. Bucke was born in 1837 in Norfolk County, England. He was graduated from McGill University in 1862, the gold medallist of his year. He was appointed to the London Asylum in 1877.

**Fewer Births and More Deaths in Montreal.**—The report of the health department of the city of Montreal for 1900 shows that although the population has enormously increased since 1891 there has been a tremendous falling off in the birth rate. In 1891 the birth-rate was 48.87 per thousand of the population; in 1900 it was 34.26. The rate for marriages for 1891 was 9.65; in 1900 it was 7.76. With a population of 218,268 in 1891, the death-rate was 24.24; while in 1900, with a population of 288,658, the rate is 25.46.

**Ontario Hospitals Association.**—The leading hospitals of Ontario have just organized an association under the above title. There is said to have been a great falling off in hospital funds recently, which may be laid at the door of the Ontario government, which recently cut down the hospital grant to 30 cents per day. The Association will seek a larger grant and also ask for powers to conduct provincial examinations for nurses' diplomas. The Association will meet annually in Toronto. Dr. John Ferguson, of the Western Hospital, Toronto, has been elected secretary-treasurer.

**Annual Meeting, General Hospital, Montreal.**—At the annual meeting of this institution held last week the report of the secretary showed that for the eight months ending Dec. 31, 1901, the ordinary income had been \$50,183 and the ordinary expenditure \$60,287. During that time 1,919 indoor patients had been treated to a conclusion. Of these 154 remained over from the previous year; and 168 remained in the hospital at the end of December, 1901. The death-rate was 7.7 per cent. as compared with the previous year, 8.5 per cent. In the outdoor department there were 20,189 consultations.

**Notices in Hospitals Respecting Charges.**—"Hospital authorities should post up notices in all hospitals stating the conditions under which patients are charged for doctors' attendance. Then the contract would be clear." This is the manner in which one of Toronto's judges delivered himself in the case of a local physician who was suing the executors of an estate for professional attendance rendered the testatrix.

The doctor was on the staff of the hospital as a junior surgeon; and the defense entered the absurd plea that because he was attached to the hospital in that capacity it was understood that he was rendering his services free. Judgment has been reserved.

**The Hospitals of the Penitentiaries.**—According to the report of the Inspector of Penitentiaries for Canada, recently handed to the Minister of Justice, the population in these institutions during the past year numbered 1382, as against 1424 for the previous year. During the year there were 23 deaths, as compared with 22 in the previous year. Special attention is called to the health of the convicts in the St. Vincent de Paul penitentiary, in Quebec Province, which the surgeon in charge has frequently admitted to be unsatisfactory. In this respect the inspector has made special investigation and finds, in his opinion, that the fault lies in a vicious drug habit. During the year about 150 pounds of tincture of opium and about 10,000 morphin pellets passed through the dispensary of the institution. The inspector, therefore, believes that the unsatisfactory state of health in the St. Vincent de Paul penitentiary can be directly traced to too much quieting and soothing medicine.

#### FOREIGN.

**Virchow's Recovery.**—The last mail brings the welcome news that Virchow's recovery is progressing smoothly. Callus has developed normally and the limb can be moved freely. He is able to sit up, but becomes easily fatigued. Five weeks have elapsed since he fractured the neck of the femur when alighting from a street car.

**Thirty-first German Congress of Surgery.**—Seven communications on the principal question, the Treatment of Wounds, have been received for this congress, which meets at Berlin, April 2 to 5. Gussenbauer, Petersen and von Mikulicz will discuss the subject of cancer; abdominal surgery will have numerous representatives.

**Prussian Appropriations for Scientific Research.**—The Prussian Budget for 1902 appropriates 20,000 marks for further study of means of prevention and early diagnosis of typhoid fever. The sum of 10,000 marks is given to the Committee for Cancer Research, and 53,000 marks are to be applied to the erection and maintenance of a cancer ward and laboratory in connection with the Charité Hospital at Berlin.

**Organization in the Profession in Switzerland.**—The various medical societies in Switzerland, speaking French, German or Italian, have combined into a central organization. The newly organized Medical Chamber is to watch over the material interests of the profession and promote the measures dictated by circumstances. It is also to transmit the wishes of Swiss physicians in questions regarding the public health and the care of the sick, to the proper civil authorities.

**Honors to Physicians Abroad.**—The golden professional anniversary of Professor Marey, of Paris, was celebrated by his friends, January 19. A portrait medallion was presented to him, the work of Dr. Paul Richer, member of the Acad. de Medecine, who is quite a fine sculptor. One of his groups received a prize at the recent exposition and salon.—Dr. A. Fraenkel's twenty-fifth anniversary as privat docent, was celebrated, January 30.—Professor A. Murri of Bologna was the recipient of a medallion and other homage on his recent silver jubilee.

**New Sanitary Law in France.**—The recently enacted public health law in France requires vaccination within the first year after birth and re-vaccination during the 11th and 21st years. Parents or guardians are held personally responsible for the execution of this law. It also has a provision enacting that whenever the mortality in any commune exceeds the average mortality in France during three consecutive years the departmental council of hygiene shall be called upon by the prefect to make an investigation, either by itself or a commission, into the sanitary conditions.

**Eddyism to be Debarred from Court Circles.**—The *Norrd. Allg. Ztg.* officially announces that Kaiser Wilhelm has expressed his disapproval of faith healing. Eddyism, and other modern fake medical methods, as nuisances (Unfug) unworthy of our day and age and of the imperial capital. In a recent conference on the subject with the chiefs of police, he asserted unequivocally that persons participating in such proceedings will be excluded from the imperial court. The *Deutsche Med. Wochenschrift* applauds this resolution, and says that it will have far more influence than any appeals to reason and common sense.

**The Plague in India.**—A correspondent who resides in North India makes a gloomy prognostication as to health conditions there. The rain has failed absolutely, not a drop having fallen from the end of August to the middle of January and in the hill reservoirs there have only been two and one-half inches of rain since the beginning of September. The springs which feed the great rivers are drying up and famine threatens. The plague is advancing by leaps and bounds. There were several cases in January in the City of Lahore and the natives were in a state of terror. What they fear is not the plague—to that they are willing to submit in a fatalistic way—but they are in terror lest they should be inoculated by force, which they think means poison. A high official of the Punjab informed our correspondent that for the last few years he had been in the habit of regarding the number of cases of plague which occurred during the first three months of the cold season as a scale by which to gauge its increase during April and May, before it is beaten down by the fierce heat. In former years the number has been below 300 in the early part of the season, rising to 10,000 in April and May. This cold season, however, the cases in the first three months of the cold season have been 24,000, and it can only be hoped that the ratio will not be the same as in former years. The plague committees are dividing up the province into districts and make frequent visits endeavoring to keep the occupiers of houses on the alert to see that there are no nuisances nor any unreported deaths.

### LONDON LETTER.

#### The Smallpox Epidemic.

The number of patients in hospital for the week ending February 8 was 1102, against 877, 870, and 1135 of the previous three weeks; 287 new cases were admitted in the week against 213, 204, and 499 in the three preceding weeks. The daily number of cases notified from February 8 to February 13 were 32, 23, 48, 58, 58 and 54. Since August 3000 cases have been admitted to Metropolitan hospitals of which 523 were fatal, 1647 were discharged cured and 1002 remained under treatment. In addition 270 cases were admitted from areas outside the metropolis.

#### Clinical Instruction in Smallpox.

The Metropolitan Hospitals Board has prepared regulations relative to clinical instruction in smallpox and recommended the local government to modify the terms of its order so as to remove the obligation of residence at present imposed on students in smallpox hospitals. The principal points are as follows: 1. No student shall be admitted until he has completed his third year, has held the offices of clerk and dresser, and obtained sanction to his attendance at the hospital. 2. The ordinary course of study shall consist of twelve demonstrations, and no student shall receive a certificate unless he has attended eight. 3. The fee shall be \$21. 4. The means of conveyance to and from the hospital shall be by the Board's steamers. 5. Every student shall wear within the hospital a suit of brown holland overalls consisting of coat, trousers and cap, which the Board will provide. 6. Any qualified doctor may attend the hospital as if he were a student. 7. To give doctors who have not leisure to attend a course opportunities of seeing smallpox demonstrations will be given from time to time, the fee being \$5 for one demonstration and \$10 for three demonstrations. 8. The rules as to disinfection and vaccination will apply to all students.

#### Air-Borne Smallpox.

The question whether the increased incidence of smallpox in the neighborhood of a hospital is due to conveyance of the disease through the air or by persons from the hospital has not been decided by epidemiologists. An investigation by Dr. Thresh, medical officer of health for Essex, made in connection with the present epidemic seems to show conclusively that the infection is air-borne. The hospital ships in the Thames are anchored on the Kent side, some 700 yards from the Essex shore, with which no communication is allowed. In 1895, when smallpox was prevalent in London and the ships were receiving numerous cases, the disease was constantly present in the neighboring district of Essex. The same fact has again been observed during the present epidemic. In August last a workman employed on the nearest point of railway to the ships was attacked. Other cases followed, notwithstanding all the efforts of the local authorities, who have a well equipped hospital. Within a radius of three-quarters of a mile of the ships no less than 8.8 of the population were attacked; beyond this

2.4 per cent., still further away .65 per cent. The evidence is further strengthened by the fact that in the part exposed to the prevailing wind 12 per cent. of the population were attacked, while in an area on which the wind rarely blew the rate was less than 1 per cent. Dr. Thresh thinks that the effect of the ships extends as far as two miles.

#### Gallantry of a Surgeon in the War.

The king has conferred the decoration of the Victoria Cross upon Surgeon-Captain T. J. Cream, 1st Imperial Light Horse. During the action with De Wet at Tygerskloof on Dec. 18, 1901, he continued to attend to the wounded in the firing line under a heavy fire at only 150 yards, after he had himself been wounded, and only desisted when hit a second time and thought to be mortally wounded.

#### Cheese Poisoning.

The medical officer of health for the city of London has reported an extremely interesting series of outbreaks of poisoning from cheese, which have occurred in various parts of London during the last three months and which have been traced to a common source. In October last certain cases of illness occurred in Bethnal Green which were supposed to have been caused by Dutch cheese sold by a local shopkeeper, who had bought it from a large firm in Finsbury. Nine persons were traced who had eaten the cheese and been taken ill. Samples were obtained from the Finsbury firm, to whom the remainder of the consignment had been returned, and who had purchased it from another city house. Many other cases occurred, and the symptoms in each were similar. No deaths resulted, and the symptoms passed off in 48 hours. The maker of the cheese did not detect anything unusual in its appearance when ripened ready for shipment. The poison was not present in all portions of the consignment.

#### The Plague.

During the week ending January 11 there were 10,368 deaths from plague in India. In the city of Bombay 234 deaths from the plague occurred during the week ending January 11, being an increase of 37 upon that of the previous week. During the corresponding period of 1901 the plague deaths were higher by 78. The director-general of the sanitary department of Egypt in his report for the week ending January 19 states that during the week 17 fresh cases of plague and 14 deaths from the disease occurred in Egypt. The population are averse to notifying plague, and as a result it is mostly by dead bodies being found that the presence of the disease is known. Out of a total of 39 cases up to the present announced at Tintah 24 have been found only after death in their houses. During the week ending January 30, 12 fresh cases of plague occurred in Mauritius and 9 deaths.

#### Statistical Report of the Health of the Navy.

This report, which has just been issued, shows that the death rate per 1000 was 7.27, an increase of 1.86 as compared with the previous year, and of 2.09 as compared with the average of the last three years. The stations which show the highest death rate are the Cape of Good Hope and West Coast of Africa (20.03), China (17.34) and East Indies (13.92); those which show the lowest are those of North America and the West Indies, 3.59. The total force afloat was 95,830. The total number of cases of disease and injury was 84,550—a rate of 882 per 1000—an increase as compared with the previous year, but a decrease of 11.2 as compared with the average of the last three years. The invalidating rate was 35.8 per 1000. There were 464 cases of typhoid fever with 124 deaths.

#### War Casualties.

An official statement just issued gives the casualties in the South African war from the commencement to the end of January, 1902, as 86,459, which, however, includes 66,000 men sent home as invalids, the great majority of whom have rejoined their regiments. The actual reduction of the military forces through the war is 25,305, which is made up as follows: Killed in action, 5314; died of wounds, 1763; prisoners who died in captivity, 103; died of disease, 11,809; accidental deaths, 598; invalids sent home who have died, 474; missing and prisoners, 439. The casualties last month (January) were 3202, which were made up as follows: Killed, 153; wounded, 362; missing, 21; died of disease, 536; accidental deaths, 36; invalided home, 2104.

#### Error in Teaching the Arrest of Hemorrhage in Ambulance Cases.

The old proverb, "A little learning is a dangerous thing," is illustrated by the correspondence evoked in the *Lancet* by a

letter of Mr. Walter G. Spencer, surgeon to the Westminster Hospital, showing that "first aid" in cases of hemorrhage rendered by persons instructed in ambulance classes often does more harm than good, and may even be responsible for a fatal result. Those who have attended such classes seem to think that they must always apply some sort of an improvised tourniquet to the limb above the bleeding point, while they have not learned the necessity of applying pressure directly to the wound. They do not understand that by applying an improvised tourniquet above the bleeding point with a degree of tightness short of absolutely controlling all circulation they cause venous obstruction. It is thus easy for a large part of the patient's blood to be forced out of a small wound. Entirely unnecessary hemorrhage is produced in this way in cases of superficial lacerated wounds, compound fractures and ruptured varicose veins. Thus, a man struck his leg against the corner of a box causing a minute puncture, such as might be made with a tenotome, in a varicosity behind the knee. His fellow workmen tied a handkerchief round the thigh sufficiently tight to cause venous obstruction, but did not apply pressure to the bleeding spot. This they had been taught. When the patient reached the hospital, the handkerchief was removed and the bleeding immediately ceased. He was profoundly anemic, and transfusion of saline solution had to be performed. Other examples given by Mr. Spencer are the cases of two men with superficial lacerated wounds near the elbows. A bandage was applied above the wound and bleeding continued severely. When they reached the hospital they were very anemic. Only the superficial veins had been divided. In the following case the improvised tourniquet seems to have caused death. A strong man, aged 20, sustained a compound fracture of the lower third of the femur. Immediately a handkerchief was tied round the thigh above the wound, and he was carried straight to the hospital. When brought in he was absolutely anemic; all the clothes of the limb were soaked in blood. The half-tight constricting handkerchief was removed, and no blood escaping a pad and firm bandage were applied to the wound. Infusion with 6 pints of saline fluid stimulating enemata, and drinks were all tried, but he died in an hour. Necropsy showed that the popliteal vessels were uninjured, only terminal branches of the profunda artery and vein were lacerated. Mr. Spencer insists that the application of direct pressure is the proper "first aid" in all cases. In the vast majority of cases there are only superficial lesions affecting small arteries and veins. In the rarer cases of hemorrhage from a large artery the wound must be pressed upon or too much blood will be lost while the tourniquet is being improvised. It only causes confusion to enter on the subject of the compression of main arteries in an elementary ambulance class.

## Correspondence.

### Letter from India.

BOMBAY, INDIA, Jan. 15, 1902.

*To the Editor:*—England has sent many of her best medical men to India for service in both army and civil hospitals. Bombay, the chief city of the Empire, is well supplied. The Grant Medical College is equipped for good work and the great hospital adjacent always teems with patients. At a surgical clinic recently held there eight capital operations were performed for various phases of tubercular infection; hip disease, amputation of forearm, peri-rectal abscess, deep cervical abscess, peritonitis, axillary glands, ankle joint and tendovaginitis of thigh. Many of the hot-climate ills are mere preparatory steps to general tuberculosis, whose ravages are fearful in the native population of the cities.

### INCREASE OF PLAGUE.

Just now plague is again attracting attention. It is increasing rapidly in other parts of India and is spreading. The Plague Commission has made its reports. Nothing but the continued persistence of the pest has been seriously determined. Several thousand more people have perished from it this year than last year. There is, however, no panic. At this great seaport the fight is steady on the part of health officers. Physicians are at a premium and some have been imported especially for plague services. They are each paid about \$300 a month. The city of Bombay provides hospitals and segregation camps for plague sufferers. There is a determined effort

to break up the overcrowding of the people in infected parts of the city. In one house 15 feet wide, 100 feet long, and five stories high, 600 people were found living in the full depth of India squalor. They were moved to a camp of thatched huts on the coast front of the city where sea air and sunshine are abundant. Segregation camps in this climate are made of bamboo, matting and thatch, a good overhead protection against rain and direct rays of the sun, with ample openings on all sides for free circulation of air. Huts are about 15 by 20 feet on the ground, about 7 feet high at the eaves, with roof about 4 feet higher at the ridge pole than at the eaves. These camps appear most effective in the fight against the plague and are in line with ancient custom. In former plagues the people of infected towns and cities would move to new sites and rebuild. They learned this method of dealing with the black death and other plagues long before the Europeans came to India.

On a great building in a big garden, which was the seat of English government until cholera drove the inmates out, is a small sign which reads, "Imperial Research Laboratory." Here Professor Haffkine conducts the plague laboratory and makes a prophylactic serum which is being freely used. In some localities physicians think it very efficient. The government pays all the expenses of the institution and sends the serum free to all who will use and report upon it.

### DEATHS FROM SERPENT BITES.

All sorts of research and serum work is done here. Typhoid, cholera and snake poisons receive special attention. The collection of cobras and vipers is large. Experiments with antivenene are constantly being tried. They follow the methods of Weir Mitchell in collecting the venom. Thousands of people perish in India every year by the bites of serpents and it is hoped that the research laboratory may discover some efficient method of neutralizing snake venom before it has killed its victim.

### QUARANTINE.

There is a plague quarantine against Bombay at all Red Sea, Mediterranean, Indian and East Indian ports. But it is modified by the time the ship has been at sea after leaving Bombay and whether she has had any outbreak of plague on board. To guard against this latter phase of the quarantine, a very careful examination is made of passengers and crew before leaving the harbor. The crew is under surveillance for at least ten days before going on the ship. The men are stripped and the port physician runs his hands over the lymphatics of neck, arm-pits and groins; looks at tongue; feels pulse and takes temperature by touch. If any have indurated glands, hot skin, quick pulse, or morbid tongues they are at once separated for re-examination. Any who are found with elevated temperature by the thermometer are rejected. If glands are enlarged also they are sent at once to a hospital for suspects, and if fever and peri-adenitis come on rapidly they are sent to the plague hospital. All passengers are examined the same way, but the cabin passengers are not stripped; a careful inquiry is made as to their general health and where they have been living. In an examination of a crew engaged for a voyage to China, I saw eight men selected for re-examination out of 160 who were examined; of those eight two were sent to hospital as suspects and six were found to have indurated glands due to other causes than plague germs. A high order of medical skill is required for these examinations. Not a ship is allowed to leave the harbor until Mayor Crimmis, M.D., health officer, and his staff have passed upon the entire ship's personnel and the disinfection of the ship and cargo. There is no perfunctory business about it, but thoughtful painstaking examination. So when a ship has been put through this course and no case of plague develops on board during the voyage of seven or eight days other ports do not hesitate to receive her.

If a passenger or member of the crew develops plague at sea he is isolated in a tent on top of the deck houses above the promenade awnings, where light and air are valued adjuvants in the treatment. He is given liquid foods. His glands are poulticed and encouraged to resist the invasion by the germs which commonly proceed from scratches and abrasions in the lower extremities. All open sores are washed with 1 to 1000

sublimate solution twice a day and the heart is supported by digitalis and strychnia. If sweats appear, fever and delirium subside, and the bubo continues to enlarge and fluctuates, recovery is hastened by incision and the evacuation of the pus. Several physicians whom I saw in Bombay have conducted plague cases to a favorable termination and in no sense despair of saving a fair proportion of their European cases. Some had plague themselves. They spoke of a tedious and tardy convalescence characterized by a great adynamia. Statistics, I am told, are not very trustworthy guides of the mortality from plague, because the death often results from the absolute neglect of the native by his friends. Good doctors told me that where they could have the cases from the start with good nursing they could save five out of six cases. Most of the deaths would occur in the pneumonic cases, which might at first be mistaken for pneumonia due to other causes. Early diagnosis is not easy. Here fevers are due to many things that do not occur in temperate climates. Sores of diver sorts are plentiful with lymphatic gland induration due to scratching simple insect bites. Oriental cases of malaria are so often seen that the real plague infection may be overlooked at the first visit. The chronicity of all these troubles and the sudden assault of the plague virus makes the diagnosis sure and prompt in the hands of cautious and skilful physicians. My inquiries in Bombay and other parts of India and at Aden lead to the inference that the serious obstacle to the control of plague by sanitation is the difficulty of breaking up the overcrowding of natives and of destroying rats and other vermin. Popular opinion has to be consulted in the East or the riots will kill more people than the plague. The Hindu will not destroy rats or other animals; it is contrary to his religion. He will die of famine before he will take food from the hand of a person of another caste and he can only be induced to enter the segregation camp by great effort and when paralyzed with fear. Now that plague and famine are both spreading in some parts, prospects are not everywhere bright in India.

#### LIVER ABSCESS.

An American surgeon visiting this country usually wants to learn something about liver abscess. At home he has been told that it is the scourge of the tropics and is quite unprepared to learn that hepatic abscess is not much of an abscess in the northern meaning of the word. It has no abscess wall like pyosalpinx. When treated by incision and drainage it discharges bloody brown pus from the usual pus microbes of northern climates and is not nearly as plentiful in numbers as dysentery, which is the guide in its diagnosis, dengue, beriberi, elephantiasis and filariasis. At Indore, at Ujjani, at Mhow and Bombay I found cases in all stages from early to late inception, with vast destruction of liver tissue and death. A soldier reported sick had fever, pain and swelling in right side; had been losing flesh for two weeks, but kept about. Here was fluctuation at the costal margin near the median line. Incision evacuated a great amount of brownish clotted material. He died in 24 hours; autopsy revealed destruction of the greater part of the right lobe. Was it a rapid destruction of liver tissue with sudden fever and prostration, or was it a chronic lesion of the organ with sudden appearance of symptoms? Liver abscess here has always an antecedent history of dysentery or disease of the alimentary tract. It is distinguished from malarial and other fevers by a daily evening rise of temperature, usually 102 F. There is always enlargement of liver if carefully looked for; rarely enlargement of spleen. Quinin dosing has been usually tried and given no benefit. There is more or less pain, always in the region of the liver: tired feeling, loss of strength and rarely any jaundice, but the complexion is muddy. Natives, unless alcoholics, never have it. The patient usually dies of exhaustion or of lung complication if the abscess is not opened. All the surgeons I talked with confirm the diagnosis by resort to aspiration and treat the abscess by drainage. The cavity is syringed out with salt solution every day. The tube is left in as long as any cavity remains to hold it. The back part of the right lobe is the favorite location of abscess, but it is sometimes found pointing beneath the costal margin and is opened there. The favored

place for introduction of aspirator trocar is between the eighth and ninth ribs in the axillary line. If pus is not found on aspiration once, they try two or three more thrusts, always with caution to avoid a long gall-bladder, portal veins and intestines. If fever does not abate and condition improve after opening one abscess, others are sought for in the same manner as the first. Chloroform is given for anesthesia throughout all India. Accidents are very rare.

HALL C. WYMAN, M.D. (Detroit).

#### Arterio-Venous Aneurysms of the Subclavian Vessels— An Addendum.

NEW ORLEANS, LA., Feb. 2, 1902.

To the Editor: I regret that in preparing the text of this contribution the very interesting and instructive case of arterio-venous aneurysm operated upon by Dr. John F. Erdmann and reported by him to the New York Surgical Society, January, 1899 (see *Annals of Surgery*, pp. 618-622, vol. 29, Jan.-June, 1899) should have escaped my observation while compiling the bibliography. It presents so many unique features and is so encouraging from the operative point of view that it is well worthy of a special abstract in connection with the analytical study of the subject which has been attempted in this contribution.

The case is one of arterio-venous aneurysm of the left subclavian vessels outside of the scalenes, and is not an aneurysmal varix as erroneously stated in the title of the report. The patient, a gymnast aged 20 years, was accidentally shot Aug. 19, 1898. The bullet (revolver, 32 caliber) entered left chest wall about 1½ inches below the middle third of the clavicle. This was followed by an immense swelling in the neck which persisted for a week or ten days. The wound healed after the first week, leaving the corresponding arm cyanotic and weak. A loud bee-buzzing murmur and thrill could be easily recognized in chest, axilla and upper brachial region. After a rest of seven weeks without improvement it was decided to cut down upon the subclavian artery, ligate it, and sew the aperture in the vein.

Under ether anesthesia, the patient was operated upon Nov. 11, 1898, three months after the date of injury. After dissection, a band of cicatricial tissue in the tract of the bullet was found encroaching upon the third division of the left subclavian. Compression of this band of scar tissue completely arrested the bruit and thrill in the affected areas. This band of scar contained the channel of communication between the injured artery and vein and was three-eighths of an inch wide and one-eighth inch long, just allowing an ordinary aneurysm needle to pass between the vessels. While dissecting this scar channel, the communication was nicked and torn through about half its width. Bleeding occurred, but was readily checked by pressure with the aneurysm needle. The needle was withdrawn and the silk tied about the communication. Hemorrhage was thus absolutely controlled. Finding it impossible to ligate the proximal side without further dissection, the clavicle was sawed at the junction of its middle and inner thirds, with a Gigli saw. Considerable difficulty was experienced even then in exposing the subclavian on account of dense cicatricial matting of the tissues. Finally the plexus and artery were freed and a ligature was applied to the third portion of the subclavian just outside of the scalenes anticus, another about the artery at the beginning of the axillary. Then a ligature was placed about the communication and the original ligature of long silk removed. Owing to the time involved and the patient's condition, the portion of the artery between the ligatures was not removed. The clavicle was wired and the wound closed without drain. Dressings were applied to keep the extremity warm. At the end of twenty-four hours, the color of the fingers and forearm was of a healthier hue than for six weeks past. At the end of the sixth day feeble radial pulsation could be felt and on the tenth day, it was quite demonstrable.

The wound healed per-primum with slight necrosis of skin. Patient left his bed on the tenth day. Union of the clavicle was not solid, but improving at time of report two months after operation. Condition of the arm as to innervation and nutrition has improved since operation. No murmur or thrill since operation.

In closing the analytical summary of the cases of arterio-venous aneurysm that the author has been able to collect from the literature it is important to revise the statistical conclusions as they are modified by the addition to the three remarkable cases recently reported by Vallas, Reboul and Erdmann which were not included in the statistics at the time when the text of this paper was written. In accordance with these new data the statistics must be amended as follows:

Total cases of arterio-venous aneurysm of the subclavian vessels reported, 18. Cases treated expectantly or without operation, 12. Operated cases, 6. Of the 12 unoperated cases, 2 died (Will's and Reboul's). Of the 6 operated, 2 died (Wattmann, Vallas).

Total mortality of the entire group, 4/18 or 22.2/9 per cent.

Mortality of the unoperated, 1/6 or 16.2/3 per cent.

Mortality of the operated, 2/6 or 33.1/3 per cent.

While these figures are interesting as showing the gross mortality of this class of lesions when viewed as a whole, they also demonstrate once more the fallacy of statistics especially of small groups, as guides, in arriving at conclusions, when the individual cases are not subjected to critical and discriminating analysis. In fact, a study of the records shows that if the two deaths included in the non-operated group had been subjected to a timely intervention before the patients had been exhausted by protracted hemorrhage and other complications they would, in all probability, have been saved. On the other hand, the two deaths which appear in the operated group could not fairly be attributed to the operation as in both instances (Wattman's, Vallas') the operations were undertaken in desperate conditions, when septic infection and other grave complications had already darkened the prospect of recovery. In trying to arrive at a fair estimate of the mortality of the operated cases, the conditions under which the interventions were undertaken and the division of the subclavian tract involved, should always be considered. Viewed in this light, the cases of Wattmann and Vallas, in both of which sepsis existed and a rupture of a varicose sac was threatened by suppuration, should be eliminated from the non-septic and non-complicated group. If separate groups of such desperate cases were collected we do not doubt that the mortality would not fall short of 95 per cent. On the other hand, the recovery of the four patients who were operated upon early (Rötter, Veiel, Erdmann and the author) in comparatively uncomplicated conditions and in the accessible portions of the artery and vein (2d and 3d divisions) demonstrates that a radical operation can be undertaken with great prospect of success and with a mortality less than in the unoperated cases in similar conditions. If we still eliminate the cases in which the profuse hemorrhage has greatly exhausted the patients and group together the type of cases represented by Erdmann's patient and my own, in which the operation was undertaken for aneurysmal varix or varicose aneurysm of the 2d and 3d division of the artery and vein, after full recovery from the effects of the primary hemorrhage and shock has taken place, we will find the operative mortality reduced to a very low percentage perfectly compatible with the aims of a thoroughly conservative surgery.

The prognosis as regards the viability of the limb still remains a debatable question to be determined by future observations; but it is evident from the results of Veiel's case and my own, that a prudent reserve must be maintained on this important point before deciding definitely as to the comparative merits of expectancy and the radical operation in the group of cases last referred to. But even from this point of view it is evident, from the lessons gathered in my case, that further modifications of the technique will justify a far more aggressive attitude than in the past.

RUDOLPH MATAS, M.D.

2255 St. Charles Avenue.

### **Tuberculophobia.**

COLORADO SPRINGS, COLO., Feb. 6, 1902.

*To the Editor:*—The recent agitation in California shows a growing tendency to make the life of a tuberculous patient miserable. It is said to be done in the interests of the people and for the good of the states that are to bar these unhappy victims. But in fact it is due to nothing less than what may be called tuberculophobia. Physicians are to a great extent responsible for this. There are too many exaggerated statements about the contagiousness of tuberculosis. Here is a city built up almost entirely by its fame as a health resort for lung patients; also because no useless restrictions have been placed upon invalids. Yet it is a fact that there are hundreds of people in Colorado who came for their health, have regained it and taken up permanent residence, who now advocate the passage of laws restricting others from regaining their health in the same way. A young man from the East went to New Mexico over a year ago. He arrived in a town where he found the people so afraid of a consumptive that it was with the greatest difficulty he secured boarding, and he was unable to find a place in the town where he could rent a room per-

manently. Disheartened and discouraged he turned eastward again, only to die. Such fear is nothing short of criminal. It seems to me that the medical profession at least should be the friend of the sick. Even consumptives are entitled to some rights.

The plan suggested of isolating them in colonies like lepers is both inhuman and uncalled for. If there is anything depressing to the mental condition of a consumptive it is in being thrown into constant contact with so many others in his own state. Whatever may be the legal right of a state to shut the citizens of other states out from its natural advantages (though we doubt the legality of it) there can be no question about the inhumanity of such a law.

Any physician knows that tuberculosis is neither contagious nor infectious as the ordinary layman understands those terms. Yet we meet with people who will walk a block out of their way to keep from passing one of these poor victims. A few days ago I was called to see a man who works at one of the hotels in this city. He had a severe cold and an accompanying cough. His first question was: "Do you think I could have caught consumption?" I inquired how. "Well," he said, "there were some men stopping here who had it." I found out that the men referred to had stopped at the hotel over night, and my patient had an idea he might have taken it from them as he would smallpox. No word but "panic" expresses the present attitude toward this disease in some quarters.

JOHN INGLIS, M.D.

### **Sugar Testing with Haines' and Purdy's Solutions.**

BUFFALO, N. Y., Feb. 17, 1902.

*To the Editor:*—The method of quantitating sugar in urine, reported by Dr. Wm. H. German, and credited to Mr. Carl Irenaeus in THE JOURNAL of February 1, apparently does not differ in principle from that of Dr. Purdy, yet the table does not seem to correspond proportionately to that published in Dr. Purdy's book. Is the "Purdy's solution" of different strength or what is the explanation? A. L. BENEDICT, M.D.

The above was submitted to Dr. German, who answered as follows:

*To the Editor:*—The proportion of urine required in this test is larger than in the Purdy test, though the same copper solution is used. This is due to the smaller bulk of the test, a slight excess of urine being required to give a perfect end-reaction.

## **Book Notices.**

A MANUAL OF CLINICAL DIAGNOSIS BY MEANS OF MICROSCOPICAL AND CHEMICAL METHODS FOR STUDENTS, HOSPITAL PHYSICIANS AND PRACTITIONERS. By Charles E. Simon, M.D., author of Simon's Physiological Chemistry, etc. New (4th) Edition, Thoroughly Revised and Enlarged. In One Handsome Octavo Volume of 608 Pages, Illustrated with 139 Engravings and 19 Plates in Colors. Cloth. Price, \$3.75 net. Philadelphia and New York: Lea Brothers & Co. 1902.

Four editions of this work have been issued in the brief space of five years. This is an indication not only of the excellence of the work, but also of what is even more gratifying, namely, a rapidly growing appreciation on the part of the general practitioner of the necessity of familiarizing himself with the methods of accurate clinical diagnosis, as it is work of this character that lies at the very foundation of all medical progress. The author presents the facts as they are known to-day in a clear and concise manner, and the frankness with which he acknowledges the many points that are not known instead of attempting to hide ignorance in misty theory, is highly commendable.

The first chapter of 137 pages is devoted to the blood, and the subject is admirably presented, with the exception of the use of the hematokrit. The author acknowledges that his enthusiasm for this instrument is dampened by the fact that he has only a hand machine, and the information which its use affords concerning the size of the corpuscles, "volumen index," etc., is therefore entirely omitted. The importance which is attached to the urine is well shown by the fact that 250 pages are devoted to its consideration. We find no men-

tion made of the rapid quantitative estimation of urinary constituents by means of the volumetric method and the centrifuge, perhaps for the same reason that applied to the hematokrit. A chapter on transudates and exudates is of much interest and value, as is one on the cerebrospinal fluid.

The colored plates are nearly all original and well executed. The work is one which should not only be possessed, but constantly used by every practitioner.

AMERICAN EDITION OF NOTHNAGEL'S ENCYCLOPEDIA.—Variola (Including Vaccination), by Dr. H. Immermann, of Basle. Vari-cella, by Dr. Th. von Jürgensen, of Tübingen. Cholera Asiatica and Cholera Nostras, by Dr. C. Liebermeister, of Tübingen. Erysipelas and Erysipeloid, by Dr. H. Lenhart, of Hamburg. Whooping Cough and Hay Fever, by Dr. G. Sticker, of Glessen. Edited, with Additions, by Sir J. W. Moore, B.A., M.D., F.R.C.P.I., Professor of the Practice of Medicine, Royal College of Surgeons, Ireland. Handsome octavo volume of 682 pages, illustrated. Cloth. Price, \$5.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

The second volume of the Nothnagel series following so soon after the appearance of the first gives promise of early completion into English of this excellent encyclopedia. From the fact that nearly half of this second volume is devoted to smallpox, vaccination and chicken-pox, it will be especially welcome at this time. It is unnecessary to say that the treatment of these subjects is exhaustive. The historic and statistical phases are valuable, especially in their relation to prevention of smallpox by vaccination. No doubter could possibly read this monograph and resist believing in the efficacy of vaccination. Besides the above, the volume contains monographs on three common every-day diseases, erysipelas, whooping-cough and hay fever, as well as a treatise on the less common disease, cholera. One is rather surprised to see hay fever treated under the title "Bostock's summer catarrh," until one recalls the fact that it was first described by an English physician, John Bostock, who reported his own case in 1819.

The editorial revision has been exceedingly well done, and this, with the numerous additions made to bring the subjects well up to date, makes the volume superior to the original German edition. We would repeat the favorable comments we made on the previous volume.

THE MENTAL FUNCTIONS OF THE BRAIN, An Investigation into Their Localization and Their Manifestation in Health and Disease. By Bernard Hollander, M.D. (Freiburg L.B.), M.R.C.S., L.R.C.P. (London). Illustrated with the Clinical Records of 800 Cases of Localized Brain Derangements and with Several Plates. Cloth. Pp. 507. Price, \$3.50. New York and London: G. P. Putnam's Son. 1901.

This work is an attempt to rehabilitate phrenology. The author thinks that the results of the investigations on the localization of functions in the brain confirm the deductions of Gall of nearly a century ago, and he makes the statement that no subject has ever been so thoroughly misrepresented even by men of acknowledged authority and no author has ever been left to such malice as Gall, notwithstanding there is not one man of scientific repute who has left anything that would indicate that he has examined Gall's chief work. We are under the impression that the recognition of Gall's services as an investigator has been more general than the author would admit. In fact, it is our opinion he has not been spoken of disrespectfully, even when the pseudo-science of phrenology has not been recognized. We do not find on perusal of the work any reason to adopt the author's opinions in regard to the minute localization which he claims, and phrenology stands in our minds in the same position it formerly occupied. The rather combative tone of the work we think is uncalled for, though, of course, in the attempt to demonstrate what has been repudiated by scientific men, some vehemence of statements might be expected. The book is well illustrated, and must have required considerable labor, and will undoubtedly be treated respectfully, even by those who do not agree with its conclusions.

A TREATISE ON ORTHOPEDIC SURGERY. By Royal Whitman, M.D., Instructor in Orthopedic Surgery and Chief of the Orthopedic Department of the Vanderbilt Clinic in the College of Physicians and Surgeons of Columbia University. Illustrated with 447 Engravings. Cloth. Pp. 650. Price, \$5.50 net. Philadelphia and New York: Lea Brothers & Co. 1901.

This, the latest work on orthopedic surgery, is also one of the best thus far published, a coincidence which is often not the case. The author considers the subject in a manner born of an intimate personal knowledge of the conditions treated,

and in a style that is both interesting and pleasant. The relative frequency with which the different conditions present themselves to the surgeon has been used as a basis for determining the amount of space to be devoted to each. The wisdom of such a division of space is questionable, for it is usually the case that the rarer conditions are the ones most difficult to diagnose, and therefore most frequently overlooked or mistaken. Thus, more space could with advantage have been devoted to such subjects as syphilitic diseases of the joints, hysteric spine, joint diseases in connection with diseases of the nervous system, some of the painful affections of the feet, etc. The common affection, such as Pott's disease, tuberculosis of the hips, lateral curvature of the spine, etc., are admirably handled, and these chapters are replete with useful and valuable suggestions.

APPENDICITIS: ITS PATHOLOGY AND SURGERY. By Charles Barrett Lockwood, F.R.C.S., Assistant Surgeon and Lecturer on Descriptive and Surgical Anatomy in St. Bartholomew's Hospital. Cloth. Pp. 287. Price, \$2.50. London and New York: Macmillan & Co. 1901.

The author in his introductory chapter makes an earnest plea for a correct use of terms, and decries the so-called classifications which are so much in use, but which are more or less confusing in that they are not self-explanatory. Chapters two and three on anatomy and histology give a clear and concise statement, particularly with reference to the blood, nerves and lymphatic supply, but the relations of the peritoneum are not as clear as might be. The succeeding chapters, up to the 15th, deal with the different types of inflammation of the appendix, and numerous clinical histories are given as examples of the particular type under consideration. The remaining chapters deal with symptoms, difficulties and errors in diagnosis, treatment, expectant and operative, incomplete operations, and lastly, the after-treatment. The author still uses a 1-60 solution of carbolic acid to keep his instruments in after they have been sterilized in the usual manner.

The work has no doubt required a great deal of time and attention, but its perusal is rendered less pleasurable on account of the citations of so many clinical cases.

A COMPLETE EXPOSE OF EDDYISM OR CHRISTIAN SCIENCE, and the Plain Truths in Plain Terms Regarding Mary Baker G. Eddy, Founder of Christian Science. By Frederick W. Peabody, Member of the Boston Bar. Paper. Pp. 68. Price, \$0.25.

This pamphlet, which is published by the author, is the most scathing exposé of Eddyism that we have seen, not only in the facts that it tells but in those it infers, and it would appear that if there were any possible chance for it the founder of this widespread cult might start a libel suit. As there has been no attempt at such it is a strong support of the correctness of the author's statements. Being an attorney Mr. Peabody undoubtedly knows just what chances he is taking in the matter. We believe that the general reading of this exposé by the profession would have a good effect. We have nowhere else seen such a thorough showing up of the fraud.

PROGRESSIVE MEDICINE, VOL. IV, 1901. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Octavo. Handsomely Bound in Cloth, 400 Pages, 13 Illustrations. Price, per annum, in Four Cloth-bound Volumes, \$10.00. Philadelphia and New York: Lea Brothers & Co.

The December number of this serial contains valuable reviews from the literature on diseases of the digestive tract by Dr. Max Einhorn; on surgery and orthopedics, by Dr. J. C. Bloodgood; on renal disease, by Dr. J. R. Bradford, the only foreign contributor; on physiology, by A. P. Brubaker; on hygiene, by Dr. Henry B. Baker, and on practical therapeutic referendums, by E. Q. Thornton. The volume as a whole maintains the general character of excellence of the series and will be a useful addition to the physician's library.

LE MALATTIE DEL SANGUE. Manuale di Ematologia. Dottor Emilio Rebuschini. Un vol. di pag. viii-432. Milano: Urico Hoepli. 1902.

This little work is one of the latest issues of the Hoepli-series reviewing the anatomy and physiology of the blood and its clinical examination and general pathology. Special attention is given to the subject of anemia, which takes up a large portion of the work. Other disorders included among blood diseases are certain parasitic disorders of the blood, and

malaria which might hardly be expected to be thus included. Of course, the work is elementary, but anyone who reads Italian will find it a valuable little work of reference on its subject.

**A TEXT-BOOK OF DISEASES OF WOMEN.** By Charles B. Penrose, M.D., Ph.D., formerly Professor of Gynecology in the University of Pennsylvania. Fourth Edition, Revised. Cloth. Pp. 539. Price, \$3.75 net. Philadelphia and London: W. B. Saunders & Co. 1901.

As the preceding editions of this work have been reviewed in these columns it is deemed unnecessary to say more of the present edition than that the author has brought it fully abreast of the times and that it therefore continues to hold its position as one of the most practical text-books on diseases of women in the English language.

## Married.

HENRY J. PARKER, M.D., of Clayton, Ill., to Miss Rhodes, of Mowcaqua, February 5.

HUGO A. KIEFER, M.D., to Miss Alice B. Campbell, both of Los Angeles, Cal., February 10.

WILLIAM S. SHOUSE, M.D., to Miss Alice C. Duston, both of Kingston, Mo., January 30.

AGUSTUS GUERTIN, M.D., to Miss Ludivinee Morin, both of Nashua, N. H., February 11.

JAMES H. CHIPMAN, M.D., to Miss Edna Manners, both of Georgetown, Del., February 8.

J. W. WYNN, M.D., to Miss Bertie Cunningham, both of Comanche, Texas, February 12.

CLARENCE S. RAMSEY, M.D., to Miss Della E. Wilson, both of Springfield, Ohio, February 11.

C. B. ALBRIGHT, M.D., Keene, N. H., to Miss Effie C. Booth, Rochester, N. Y., February 11.

CHARLES H. SCHOFF, M.D., of Media, Pa., to Miss Helen G. Duffee, of Chester, February 11.

GEORGE E. PENDER, M.D., to Miss Grace M. Sherwood, both of Portsmouth, N. H., at New York, February 9.

## Deaths and Obituaries.

**George A. Shurtleff, M.D.** Vermont Medical College, Woodstock, 1845, formerly professor of mental diseases and medical jurisprudence in the medical department of the University of California, president of the California State Medical Society in 1872, delegate to the International Medical Congress in 1876, member of the American Medico-Psychological Association and of the State Medical Society, who was for eighteen years medical superintendent of the State Insane Asylum at Stockton, died in that city, February 11, aged 82. He had retired from practice about nine years ago because of his failing health, and for the past five years had been an invalid.

**Joseph B. Holland, M.D.** Dartmouth Medical College, Hanover, N. H., 1866, and Columbia University, New York, 1867, died of muscular atrophy in Boston, Mass., February 14, aged 61. He had been a prominent citizen of Galesburg, Ill., since 1870, and, having retired from the practice of medicine because of his health, became a wholesale publisher of medical books.

**Levi Cooper Lane, M.D.** Jefferson Medical College, Philadelphia, 1851; member of the Royal College of Surgeons, England; founder of the Cooper Medical College and of Lane Hospital, San Francisco; a member of the American Medical Association, died at his home in San Francisco, February 19, aged 70.

**William McKean, M.D.** Jefferson Medical College, Philadelphia, 1867, died of cancer of the liver and stomach, February 12, at his home in Canal Dover, Ohio, aged 64. He was a member of the Tuscarawas County Medical Society and of the Northeastern Ohio Medical Association.

**Dexter C. Holly, M.D.** University of Michigan, Ann Arbor, 1853, a prominent physician of that state, formerly president of the Grand Rapids Medical Society, who had retired from practice a few months ago, died at his home in Ann Arbor, February 13, of heart disease, aged 76.

## Benjamin Franklin Pope, M.D.

By the death of Colonel Pope, which occurred in Manila, February 14, and was noticed in the last issue of THE JOURNAL, the Medical Department of the Army loses one of its most prominent members. He was born in Rome, N. Y., on Feb. 24, 1843, and, therefore, at the time of his death was within ten days of being 59 years of age. He entered Hamilton College, New York, and studied there two years, being a class-mate of the present Secretary of War. He was graduated from Albany (New York) Medical College, in June, 1864, and immediately entered his country's service as assistant surgeon of the 10th New York Heavy Artillery. He served in the trenches in front of Petersburg and in the Shenandoah Valley in Sheridan's campaign; was chief of the field hospital at Bermuda Hundreds, in the provisional department of Virginia and North Carolina, and was afterward in charge of the Washington Hospital at Petersburg after the evacuation of the town, and until the close of the war. At this time, although he was young in years and in professional experience, he manifested a high degree of professional skill and of executive ability. He was mustered out of the volunteer service, July 19, 1865, was appointed lieutenant and assistant surgeon in the Regular Estab-

BENJAMIN FRANKLIN POPE, M.D.

lishment, May 14, 1867; was made captain and assistant surgeon in 1869, and received his majority on Sept. 16, 1885. He was the first to notice and report the fungous growth resulting in "Madura foot" and reported a case in which he amputated the foot for this condition. To him also belongs the credit of establishing the circulating library for the army. At the outbreak of the Spanish-American war he was made Lieutenant-Colonel and Chief Surgeon of the 5th Army Corps, on May 9, 1898, and served throughout the war as chief surgeon under General Shafter, having entire medical charge of the Department of Santiago. He was mustered out of the volunteer service on Oct. 31, 1898, and on December 21 of the same year received his promotion to Lieutenant Colonel and Deputy Surgeon-General. On Jan. 1, 1902, he was made Colonel and Assistant Surgeon-General. Dr. Pope's chief contributions to medical literature were: "Trichinosis in the Army," 1884; "Mycetoma, the Fungous Foot of India," 1896, and "A Plan for the Organization of a Medical Department for War Service in a United States Volunteer Army," read before the Association of Military Surgeons of the United States in 1900.

**Oscar W. Peck, M.D.** University of Vermont, Burlington, 1880, member of the Burlington Clinical and Vermont State Medical Societies, who had been state senator and Surgeon-General of Vermont, died, February 16, at Winooski, aged 47.

**Jesse Myer, M.D.** New York University, 1845, who had practiced medicine in Kingston, N. Y., since his graduation, died, February 16, at his home in that city, aged 80, from injuries received in a fall on an icy sidewalk.

**Howard Jennings, M.D.** Hospital College of Medicine, Louisville, Ky., 1886, of Savannah, Ga., died February 11, at El Paso, Texas, on his way home from Arizona, whither he had gone in pursuit of health.

**Thomas H. Smith, M.D.** Cincinnati Medical College, Ohio, 1855, died at his home in New Philadelphia, Ohio, February 19, after an illness of many months with heart disease, aged 78.

**William H. Clark, M.D.** New York University Medical College, 1882, of Bellingham, Mass., aged 55, was killed, February 15, by a train while he was driving across the track.

**William M. Ridenour, M.D.** Western Reserve University, Cleveland, Ohio, 1895, died of pulmonary tuberculosis at Las Cruces, N. M., recently.

**N. J. Newell, M.D.** Reform Medical College of Georgia, Macon, 1854, died at his home in Anderson, S. C., February 14, of heart disease.

**Louis Z. LaJoie, M.D.** Laval University, Quebec, 1894, died after a long illness, February 13, at his home in Haverhill, Mass., aged 34.

**Joseph H. Baker, M.D.** University of Pennsylvania, 1854, died of Bright's disease, February 12, at his home in Taboro, N. C.

**James B. Crane, M.D.** South Carolina Medical College, Charleston, 1851, of Batesville, Ark., died suddenly about February 6.

**John T. Dooley, M.D.** New York University, 1888, died of pneumonia at his home in Manchester, Conn., February 15; aged 34.

**Richard C. Mackall, M.D.** University of Maryland, 1847, died at his home in Elkton, Md., February 16, of paralysis, aged 80.

**John P. McClanahan, M.D.** Jefferson Medical College, Philadelphia, 1854, died recently at his home in Alexis, Ill., aged 78.

**Lyman J. Adair, M.D.** Rush Medical College, Chicago, 1870, died February 14, at his home in Anamosa, Iowa, of pneumonia.

**George S. Glenn, M.D.** Bellevue Hospital Medical College, New York, 1874, of Morrilton, Ark., died February 9, aged 48.

**P. D. Flower, M.D.** University of Pennsylvania, 1869, died at his home in Albion, Pa., February 9, of apoplexy, aged 72.

## State Boards of Registration.

**Iowa State Examination.**—The Iowa State Board of Medical Examiners held quarterly examination for license, at Des Moines, January 21 and 22. The number of subjects examined in were 8; total number of questions, 80; percentage to pass, 75. There were 18 applicants, of whom 14 passed:

## New Instrument.

### A SUTURE HOLDER.

A. E. BENJAMIN, M.D.

MINNEAPOLIS.

All operators have found some inconvenience in the use of the forceps to hold sutures as they are introduced in abdominal wounds. A great many forceps are necessary if each suture is to be held at each end by a separate forceps. Much time is consumed in clamping and reclamping the forceps, on the part of the operator and his assistant.

I have devised an instrument which may be used for all linear incisions when the sutures are introduced before they are tied. The above illustration represents the two suture holders, A and B, in operation. C and D represent the angles

of incision, and the sutures are shown as they pass out of the skin to the loops on the plates.

Each instrument consists of a plate of steel about four inches long, three-fourths of an inch wide, and one-eighth of an inch thick. Upon this plate are soldered loops of steel wire, placed in a manner so there is sufficient spring to retain the sutures, and as each successive suture is introduced, the operator and his assistant on their respective sides of the patient, quickly slip the ends of the sutures between the loops. These loops being soldered at an acute angle on the plate, and with an obtuse angle next to the wound, any pulling in the direction of the wound tightens the grasp of the loops upon the suture, making it impossible to get out of the grasp of the loop. Yet, when these sutures are to be tied successively, a little pull in the opposite direction and raising the suture at the same time, easily loosens it, so as to be tied.

The plates are placed at a sufficient distance from the edges of the wound, so that they do not interfere in any way with the introduction of the various sutures. The advantages claimed for this instrument are as follows:

1. The economy of time while the sutures are being introduced.

2. It holds the sutures separately, not allowing them to get mixed up or twisted.

3. It saves the unclamping and reclamping of forceps, which are often used to hold the ends of the sutures or avoids the use of many forceps to retain the individual sutures.

4. The operator himself, without loss of time, quickly shoves the end of the suture between the loops without having to loosen his hold upon it.

5. The two instruments may be raised after all the sutures are introduced to approximate the edges of the wound, showing at once any failure of an individual suture to approximate the opposing surfaces, and this suture can be quickly identified, removed and reintroduced properly.

I have been using these suture holders in nearly all my abdominal operations for the past six months, and have found them a great convenience and saver of time in this work.

## Miscellany.

**Diagnosis of Insufficiency of the Pylorus.**—THE JOURNAL has mentioned Queirolo's method of determining the outlines of the stomach. A small rubber balloon is fastened to the end of a sound which branches above. One branch connects with a Marey drum, the other has a faucet to shut off the air. After the balloon is partially inflated and communication with the outer air is closed by the faucet, percussion over the stomach causes the index to vibrate at the slightest touch, while it does not move when the percussion passes beyond the limits of the stomach. It is possible by this means to locate the outlines of the stomach with extreme accuracy if the pylorus is normal. In

case of insufficiency of the pylorus, on the other hand, the air escaping through the pylorus deprives the stomach of the conditions necessary to enable the effect of the percussion to be transmitted from the stomach walls to the balloon and in turn to the index. Hence the index does not stir in case of insufficiency of the pylorus, even when the percussion is applied directly over the stomach. The insufficiency may be intermittent or total. In some cases the index moves at certain times and is immovable at others, thus allowing the complete supervision of the behavior of the pylorus under varying conditions. Queirolo stated in his communication on the subject at the recent Italian Congress of Internal Medicine, that these tests fail only in obese subjects or when there is an excessive tendency to borborygmus on the slightest occasion.

**The Bibliographia Medica.**—Professor Richet, one of the editors of the *Bibliographia Medica*, remarked in a recent editorial in his *Revue Scientifique*: "Americans appreciate the advantages of organized classification of contemporaneous medical bibliography better than Europeans. Almost all the subscribers to the *Bibliographia Medica* are in America, principally in the admirable libraries of American Universities. The Germans, Russians, Italians and even the French, have been strangely indifferent." He continues, "If even one-half of the university libraries in the world would subscribe to the *Bibliographia Medica*, the work could go on, as it is not published for profit." It is a strictly international undertaking, and if German and American works are in the majority in the index, it is merely because the medical output is larger in Germany and the United States than in other countries. The Newberry Library of Chicago wrote to urge the continuance of the work "at any price," gladly agreeing to pay any subscription that might be asked.

**Subarachnoid Serum Treatment of Tetanus.**—Professor Penna, of Buenos Ayres, is convinced that tetanus is essentially an affection of the spinal cord rather than of the brain. For this reason he injects the antitetanus serum into the subarachnoid cavity and reports in the *Semana Medica* of October 31, five patients thus treated. The amount of Pasteur antitetanus serum varied from 30 to 40 c.c., so that the different patients received a total of from 100 to 240 c.c. All were severe cases of traumatic tetanus. Three patients recovered under daily injections of the serum with a slow, regular subsidence of the symptoms in three to seven days. The other two patients died of an intercurrent pneumonia, but the tetanic symptoms had already subsided, the limbs were relaxed and voluntary movements were possible. As much as 60 c.c. were injected once in a peculiarly severe case. Penna had previously tried antidiphtheria serum in subarachnoid injections, but found that the course of the tetanus was not affected unless possibly the disease was aggravated. He always withdraws an approximately corresponding amount of cerebrospinal fluid, and no inconveniences were ever noted from this technique.

**Gersuny's Treatment of Furuncles and Carbuncles.**—Instead of waiting for an abscess to ripen, Gersuny incises at once and drains with a tube or rubber tissue, after scraping out the necrotic substance. This prevents the spread of particles to induce further abscess formation. He treats a carbuncle on the same principle, as he believes that the tension of the skin above forces the contents of the abscess out into the surrounding tissues, thus favoring the spread of the infection. He is careful to avoid making a large hole, which takes long to heal, but makes his incisions like the spokes of a wheel, leaving the center intact. He cures through each one of the incisions and keeps them open with iodoform or dermatol gauze at first and later with rubber tissue. The lesion heals usually in a week.

**The Physician in Politics.**—As a matter of fact, the doctor is under a greater obligation to actively interest himself in matters pertaining to local government, public education and other civic service than almost any other citizen in his community. His obligation is greater because of his fitness for responsibility through education, high ideals of character and the close relationship he sustains to the families and homes of the community in which he lives. He can not be a successful

practitioner without some measure of scholarly attainment. A physician's knowledge is rarely confined to pathology and therapeutics. He has been in the college atmosphere. He has a taste for books and a desire to explore the wide fields of scientific investigation. He is generally a man of liberal culture and refined instincts. His profession also gives him wide knowledge of men. Such a man is needed in the responsible civic positions in every city and town. Public service of this character need not carry with it any loss of professional prestige or any sacrifice of personal interest. It is true that the doctors are drafted for school boards and other positions closely related to educational affairs in many towns, serving in such capacities with great credit to the profession and great profit to the schools. But the doctor is needed in larger fields of civic usefulness. It is an obligation he should not be permitted to escape.—*Recrd-Herald* (Chicago), February 16.

**Experimental Spinal Cocainization.**—Experiments on dogs and frogs are described in the Russian *Med. Obos.* for August, which show that a solution of cocain injected into the lumbar subarachnoid space is more liable to reach the medulla oblongata the larger the amount of fluid injected, and the more the head is lowered. It penetrates into the gray matter by diffusion, by osmosis and also by the lymphatics. The analgesia is more profound than in morphin-chloroform narcosis. The terminals of the nerves feel the analgesia more than the trunks. The intestinal peristalsis is very much diminished and the abdominal organs become anemic. If the animal is suffocated after it is cocainized, the clinical picture of the asphyxia is much less pronounced than usual, which suggests that the conducting power of the spinal cord is paralyzed or much diminished. The arterial and venous blood pressure was increased, the pulse rising from 68 to 108. The blood pressure increases with the smallest amount of cocain injected into the blood. Halbreich deduces the practical conclusions from his research that: the amount of fluid should be restricted to 1 c.c.; that the injection should be made very slowly, and persons with short bodies, especially children, should be excluded from spinal cocainization on account of the danger that the fluid may reach the medulla oblongata. Weak heart action is not a contra-indication and repeated injections at brief intervals are well tolerated.

## Societies.

### COMING MEETINGS.

- Medical Association of the Missouri Valley, Lincoln, Neb., March 20, 1902.
- Medical Association of the District of Columbia, Washington, April 1, 1902.
- Tri-State Medical Society of Iowa, Illinois and Missouri, Chicago, April 3-4, 1902.
- Tennessee State Medical Society, Memphis, April 8, 1902.
- Florida Medical Association, Tampa, April 9, 1902.
- Western Ophthalmological and Oto-Laryngological Association, Chicago, April 10-12, 1902.
- Medical Association of the State of Alabama, Birmingham, April 15, 1902.
- Medical Society of the State of California, San Francisco, April 15-17, 1902.
- Medical Association of Georgia, Savannah, April 16, 1902.
- Mississippi State Medical Association, Jackson, April 16, 1902.
- South Carolina Medical Association, Spartanburg, April 16-17, 1902.
- Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.
- Association of American Physicians, Washington, D. C., April 29-30, 1902.
- American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

**Rock Island County (Ill.) Medical Society.**—This is the name of the new society incorporated February 7.

**Chehalis County (Wash.) Medical Society.**—This is the name of a new society recently organized at Aberdeen, with Dr. George W. Overmeyer as president and Dr. J. William Seamell, secretary.

**Pasadena (Cal.) Medical Society.**—The annual election, February 12, resulted in the election of Dr. Henry H. Sherk, president; Dr. Stanley P. Black, vice-president; Dr. John E. Janes, secretary and treasurer.

**Shelby County (Tenn.) Medical Society.**—This new organization was formed at Memphis, February 12, with temporary officers and will be the local society affiliated with the American Medical Association.

**Redlands (Cal.) Medical Society.**—This Society elected the following officers in January: President, Dr. Charles C. Browning, of Highland; vice-president, Dr. Gayle G. Moseley; secretary and treasurer, Dr. J. E. Payton.

**Bay County (Mich.) Medical Society.**—The annual meeting in Bay City, February 10, elected Dr. Virgil L. Tupper, president; Dr. Everett A. Hoyt, vice-president; Dr. Morton Gallagher, secretary; Dr. Charles H. Baker, treasurer.

**St. Joseph County (Ind.) Medical Society.**—The annual election, January 27, resulted as follows: President, Dr. William G. Wegner; vice-president, Dr. James H. Cannon; secretary, Dr. Harry F. Mitchell; treasurer, Dr. Charles M. Butterworth.

**Platte County (Neb.) Medical Society.**—This new Society elected the following officers, February 14: Dr. H. J. Arnold, Columbus, president; Dr. J. C. McKinley, Humphrey, vice-president; Dr. Berthold C. Tiesing, Columbus, secretary; Dr. H. A. Hansen, Columbus, treasurer.

**New York Neurological Society.**—The following officers have been elected for the ensuing year: President, Dr. Joseph Collins; vice-presidents, Drs. J. Arthur Booth and Frederick Peterson; recording secretary, Dr. Joseph Fraenkel; corresponding secretary, Dr. Frank Hallock; treasurer, Dr. Graeme M. Hammond.

**Fox River Valley (Wis.) Medical Association.**—At Green Bay, January 21, these officers were elected: President, Dr. Charles D. Boyd, of Kaukauna; vice-presidents, Drs. Daniel W. Harrington and Bertha V. Thomson, of Oshkosh; secretary and treasurer, Dr. James S. Reeve, of Appleton; censor, Dr. Theodore J. Redelings, of Marinette.

**Kendall County (Ill.) Medical Society.**—This new organization was formed, February 11, at Yorkville under the guidance of Dr. Edmund W. Weis, of Ottawa, secretary of the State Society. The following officers were elected: Dr. Julius A. Freeman, Millington, president; Dr. William M. Hanna, Lisbon, vice-president; Dr. Robert A. McClelland, Yorkville, secretary.

**Randolph County (Ind.) Medical Association.**—The meeting of this Society in January resulted in the election at Winchester of Dr. Forrest A. Chenoweth, president; Dr. Clifton M. Kelley, vice-president; Dr. W. O. Hinshaw, of Lynn, secretary; Dr. John T. Chenoweth, treasurer; Dr. James S. Blair, of Lynn, Dr. Joseph J. Evans, Dr. William Commons, Union City, censors.

**Eastern Ohio Medical Society.**—At Steubenville, January 23, this Society elected as president, Dr. Arthur B. Holland, Wellsville; vice-presidents, Dr. Joseph J. McCoy, Steubenville; Dr. William L. England, Jewett; Dr. Brady O. Williams, Martin's Ferry; Dr. William M. Calhoun, East Liverpool; secretary, Joseph F. Purviance, Steubenville; corresponding secretary and treasurer, Dr. James C. M. Floyd, Steubenville.

**Ramsey County (Minn.) Medical Society.**—At the annual election and banquet, January 27, this Society elected Dr. John L. Rothrock, president; Dr. Angus Macdonald, vice-president; Dr. Ethelbert F. Geer, secretary; Dr. Frederick Leavitt, treasurer; Dr. Alvah F. Whitman, necrologist. The *St. Paul Medical Journal*, owned by the Society, was reported to be a profitable enterprise. The editor, Dr. Burnside Foster, and business manager, Dr. H. L. Taylor, were warmly praised for their excellent management and for the high class of the journal.

### NEW YORK COUNTY MEDICAL ASSOCIATION.

*Stated Meeting, held Jan. 20, 1902.*

The President, Dr. Parker Syms, in the Chair.

#### Primary Sarcoma of the Pancreas.

DR. EDWARD SCHNAPER presented a primary sarcoma of the tail of the pancreas, taken from a woman of 53, who had been operated on by Dr. M. S. Kakels under the belief that he was dealing with a tumor of the left kidney. The tumor was inoperable. It was large and soft, and presented firm nodules on its surface, which, on microscopic examination, proved to be lymph nodes that had been incorporated in its growth. The left kidney and spleen were not involved in the neoplasm. It was worthy of note that although the pancreatic tissue was

almost completely destroyed, repeated examinations of the urine failed to show any sugar.

DR. M. S. KAKELS said that it was exceedingly difficult to make a diagnosis of a tumor of the pancreas unless the growth were palpable. This woman had been sick about six months, and he had done an exploratory laparotomy in the expectation of finding a sarcoma of the kidney. He had been able to find in the literature only 20 tumors of the body, and 4 of the tail of the pancreas.

#### Diabetes Mellitus.

DR. C. E. NAMMACK opened a symposium on diabetes with this paper. With regard to the diagnosis, he said that even a change from blue to green in the copper-test solution called for further investigation. By repeated filtration through animal charcoal one could remove the other substances likely to reduce the copper, and leave the sugar alone in solution. The combination of chronic gastritis, alcoholism and chronic hepatitis furnished by far the largest number of cases of non-diabetic glycosuria. When the function of sugar assimilation was depressed the sugar taken as food would appear temporarily in the urine. The majority of cases of transient glycosuria presented no other symptom than the presence of sugar in the urine. It was merely a perversion of function yielding readily to treatment, and not accompanied by severe symptoms. It was very different from true diabetes. Under the influence of diabetes the tissues melt down, emaciation develops, and life is often terminated in a coma which is the result of a true auto-intoxication. True diabetes was a frequent disease in this city, and it appeared to be on the increase as a result of our strenuous life. Out of 202 deaths occurring in the boroughs of Manhattan and the Bronx, 54 were in Jews and 51 in people of Irish nativity or parentage, but his personal experience did not bear out the idea of the compiler of these statistics, that this disease was common in these races because of their breeding in and in. Grief, fright, joy and anger or anxiety, if protracted, exerted a marked influence. The association of insanity with diabetes was so marked as to be more than a mere coincidence. Gouty glycosuria was more or less persistent, and was liable to pass into the graver condition of diabetes mellitus. Diabetes mellitus was of frequent occurrence in obese individuals, and this form was more amenable to treatment than that variety associated with emaciation. Much had been written about pancreatic diabetes, but this disease occurred without injury to the pancreas, and extensive disease of that viscus might occur without diabetes. The perverted metabolism theory supposed an inability on the part of the muscles and glands to appropriate the sugar brought to them by the blood. It was improbable that all cases of diabetes were dependent upon a single cause—indeed, it was probable that diabetes mellitus was a disease of nutrition, sometimes acute, but generally chronic, characterized by the presence of dextrose in the urine, by polyuria and by a progressive loss of flesh and strength.

#### Surgical Aspect of Diabetes.

DR. ARPAD G. GERSTER read this paper. He called attention to the observation of Dr. Theobald Smith, that pyogenic bacteria thrive best in media containing between .2 and .5 per cent. of sugar, or that percentage found in the blood of diabetics. The products of faulty assimilation circulating in the blood of the diabetic caused a lowering of the vitality of the tissues, and led to a condition similar to premature senility. For this reason the tissues were especially vulnerable to the onslaught of microbes. It was well known that in a minority of persons wounds of all kinds show a tendency to suppurate, and it was possible that in such persons there was a latent diabetes, or at least a condition of the system which would finally lead to diabetes. Furunculosis and carbuncle were relatively common in diabetics, more particularly in persons of middle age having glycosuria. The favorite location for carbuncle was on the dorsum, and he had seen one case in which one enormous carbuncle extended from the occiput to the sacrum. The treatment should consist in early, free multiple incisions. Slight traumatism in diabetics often gave rise to gangrene. The treatment should consist in measures for

improving the circulation of the part. Perforating ulcer, occurring in a diabetic, showed a special tendency to lymphangitis and phlegmonous inflammation. The non-infectious form of gangrene arose from the existing arteriosclerosis. An evanescent limping, or a peculiar painful sensation or numbness coming on after remaining quiet for a short time, should be looked upon as the precursor of gangrene. Gangrene of the extremities was about four times more frequent in men than in women. The mortality was about 50 per cent., death often occurring in coma. In the non-infectious cases of gangrene without fever, the part affected should be kept dry and elevated, and when the line of demarcation had formed no operation should be done without stringent necessity. The point at which to do an amputation must be determined by the amount of arteriosclerosis present. In the infectious cases, it was often necessary in order to avoid contact infection, to perform a high amputation. In operating on such cases there was danger both from the anesthetic and from the occurrence of diabetic coma. The operation should be done in the morning, so that there need not be too much fasting beforehand, and before and after the anesthesia the patient should receive 2 drams of bicarbonate of soda and 10 grains of bicarbonate of potassium. In amputations, it was better to use short flaps and keep an open wound, avoiding sutures.

#### Diabetic Affections of the Eye.

DR. S. BUSBY ALLEN said that one of the early symptoms of diabetes affecting the eyes was a partial paralysis of the ocular muscles, most commonly of those innervated by the third nerve. These paralyzes bore no constant relation to the gravity of the disease. Paresis of accommodation usually occurred early, and if rapidly progressive in a person under 35, was strongly suggestive of glycosuria. A cataract in a young person, ripening within a few weeks, and appearing in both eyes was almost certainly of diabetic origin, but in older persons a diabetic cataract presented no characteristic features. Diabetic retinitis closely resembled the retinitis of Bright's disease. It occurred early and was one of the causes of diabetic amblyopia. This form of amblyopia was in all respects like the amblyopia of tobacco or alcohol, and was often an indication of impending diabetic coma.

#### Prognosis and Treatment of Diabetes.

DR. ABRAHAM MAYER said the favorable symptoms were: 1, advanced age at the commencement of the disease; 2, long duration of the disease without serious complications or marked emaciation; 3, traumatic or syphilitic origin; 4, absence of the disease in other members of the family; 5, association with obesity, or with gout or the uric acid diathesis; 6, a mild glycosuria along with a fair tolerance for carbohydrates; 7, rapid excretion of sugar with increasing tolerance for the carbohydrates; 8, conditions of life favorable to proper dietetic and hygienic management, and 9, the development of the disease about the time of the menopause. The unfavorable symptoms were: 1, development early in life; 2, early loss of flesh and strength; 3, severe gastro-intestinal symptoms; 4, diabetic gangrene; 5, presence of diabetes in other members of the family; 6, the occurrence of phthisis as a complication, particularly if associated with a cessation of the glycosuria; 7, a large excretion of acetone and an increase of ammonia; 8, unfavorable conditions of life, and 9, the coexistence of organic disease of the pancreas. In the treatment, our chief aim should be to increase the power of the system to assimilate carbohydrates, and it should be ever kept in mind that no method of treatment which excluded dietetic management was of any avail. Fortunately a diabetic dietary could now be made varied and palatable. The patient should at first be placed upon a standard rigid diet, composed of albumin, fats and a very little alcohol. If the type of the disease were mild, the patient would become sugar-free in a few days, but in the more severe forms it might be necessary to also reduce the nitrogenous elements of the food. When a diabetic continued to excrete sugar for some time his tolerance for carbohydrates diminished, and conversely, when a diabetic was kept sugar-free for a considerable time by a strict regimen his tolerance for carbohydrates increased very

materially. Diabetics usually suffered most from the exclusion of bread from the dietary, and he had found that walnuts could often be advantageously substituted. The diabetic should be warmly clad, and, while taking open-air exercise, should have an abundance of rest for both mind and body. Opium and its alkaloids allay the nervous irritability and improve assimilation. Half a grain should be given as the initial dose, three times a day after meals, and should be cautiously increased, its constipating effect being counteracted by the administration of rhubarb or cascara. The speaker said that he had had the honor some years ago to advance the bacterial theory of diabetes, and in accordance with that view he had treated suitable cases with the bichlorid of mercury. This had given him better and more lasting results than any other medicinal treatment.

DR. J. C. BIERWIRTH, Brooklyn, said that, according to his experience, there were many cases of glycosuria in which there was no increase in the quantity of urine and no augmentation of the specific gravity. For example, he had just seen a case in which only 57 ounces of urine were voided daily, and the specific gravity of this urine was only 1018, though it contained 3 per cent. of sugar. The importance of recognizing this fact was obvious when one recalled that very many physicians are in the habit of omitting to test for sugar if the specific gravity of the urine is not over 1020. He was not quite so sanguine as Dr. Mayer regarding the results of treatment in diabetes. When thirst, polyuria and beta-oxybutyric acid were present, the physician could do very little, but in the earlier stages he could accomplish a great deal.

DR. JAMES J. WALSH thought it not improbable that in the future we would have to admit the contagiousness of diabetes. The general practitioner could hardly be expected to examine the urine of every patient, but when a young man complained of soreness of the gums, of fatigue on slight exertion, or of loss of sexual power, the urine should certainly be examined for sugar.

DR. N. E. BRILL pointed out that Dr. E. Libman, of New York, had discovered that when the percentage of sugar in culture media was the same as in the blood of diabetics the bacteria grown on such media immediately precipitated the peptones. This raised the question as to whether such a precipitation of peptones might not possibly explain the frequent occurrence of thrombosis and furunculosis. He declared that Dr. Mayer's views regarding the action of bactericides in diabetes were purely speculative, and had never been substantiated by pathologic research. Bichlorid of mercury was certainly sometimes beneficial in diabetes, but only, according to his own experience, in syphilitic cases.

DR. ALEXANDER LAMBERT remarked that as peptone was only found in the portal vein, the theory of the precipitation of peptones might well be characterized as fanciful.

DR. MAYER, in closing, said that he had found both husband and wife diabetic in nearly 8 per cent. of the cases he had investigated, and he was a firm believer in both the contagiousness and infectiousness of diabetes.

#### CALIFORNIA ACADEMY OF MEDICINE.

*Regular Meeting, held Jan. 28, 1902.*

##### Myositis Syphilitica.

DR. D. W. MONTGOMERY reported this case and presented the patient, who was a man aged 30 years with a history of venereal sores three months previously. He came under the author's care July 26, 1901, when he was suffering with a roseola and general adenopathy. In August a painful tender swelling of the left sterno-cleido-mastoid muscle throughout its course occurred with some interference with function, causing stiff neck. The swelling of the muscle was most marked in the middle third of its course, causing a decided bulging of the side of the neck. This subsided, but reappeared to a less extent five months later, December, 1901. On Dec. 13, 1901, there was density of the muscle in its middle third, but extending up and down almost its entire length, pain only where the muscle was put on the stretch, and a little tenderness. There was a packet of enlarged lymphatic nodules both in front and be-

hind the muscle and extending beneath it at the point where the muscle was most affected. The patient also complained of pains in the left shoulder and in the left elbow, and consequent lack of strength in the whole left upper extremity, with pains in both ankles and both knees. On the cutaneous surface there was a well-marked papulo-crustated syphilid. The patient was given 10-grain doses of potassium iodid, associated with 30-drop doses of fluid extract of senna to overcome a coincident constipation. He was also directed to rub mercurial ointment into the skin over the affected muscle. On Jan. 28, the affection of the sterno-cleido-mastoid muscle had improved, but the swelling of the lymphatic nodules was more pronounced. There was so much pain in the bends of both elbows that he could not completely extend either arm, and there was pain in the left knee. The papulo-crustated syphilid was still present.

##### Primary Luetic Sore on Lower Lip.

DR. HOWARD MORROW reported a case and presented the patient, a young woman. The sore was of five weeks' duration and began as a fissure, later becoming nodular. There was enlargement of the neighboring lymphatic glands. Under treatment the swelling was rapidly decreasing.

##### Hepatic Abscess.

DR. F. B. CARPENTER presented the liver of a woman 35 years of age, who had lived in Mexico for the past two years. Reported well until six months ago when she was taken sick with chills and fever and said to have had malaria. This condition continued until she came to San Francisco about one month ago. Patient was confined to her bed at the time and profoundly jaundiced, appetite gone, bowels constipated and patient had lost in weight from 80 to 120 pounds. There was a history of tumor having been present about three weeks before in the region of the gall-bladder. Tumor suddenly disappeared, and was followed by a discharge of blood and pus from the rectum. Examination showed lower border of the liver to be about three inches below the costal margin and somewhat tender to the touch. Pain had been continuous but never spasmodic; patient had acquired the morphin habit to a slight degree. There was no history of diarrhea at any time and but slight vomiting; sweating had been more or less persistent from the beginning. Leucocyte count showed 35,000; no ameba was found in intestinal discharge. The abdominal veins were well defined. The diagnosis lay between empyema of the gall-bladder and hepatic abscess with rupture into the intestinal tract. Operation showed that an abscess the size of two fists existed in the right lobe of the liver, that the under surface of the abscess cavity was formed by the coherent stomach and colon. The cavity was filled with a thick, stringy and dark-colored pus containing blood, broken-down liver substance and evidently some mucus. Autopsy on the fourth day showed that the adherent stomach was in direct communication with the abscess through a perforation in its posterior wall. The gall-bladder was contracted, thickened to about one-half inch, and its cavity and duct nearly obliterated. The case was thought to be one of tropical abscess, though a hasty pathologic examination by Dr. Philip King Brown had developed no evidence of ameba in any portion of the abscess walls, though it was most likely that that was its original cause. The entire liver was studded with abscesses of all sizes, from a pinhead to a marble.

##### The Species of Blister Beetles Inhabiting the United States.

DR. F. E. BLAISDELL exhibited and called attention to a collection of blister beetles that were indigenous to the United States. They were of special interest to the physician on account of the cantharidin which they contained, and the vesicating power which they possessed, which was utilized as a counter-irritant and also as an internal remedy in several diseases. To the entomologist they were of interest because of the phenomena of hypermetamorphosis that they presented during their development. These coleopterous insects belonged to the family meloidae, which comprised 26 genera and about 191 species. Out of the 47 species of the genus cantharis found in our fauna, 29 are found in the State of California. There was only one official species, the cantharis vesicatoria. It was found

in southern Europe about the Mediterranean, and in the southern provinces of Russia, those from the latter being the most esteemed. A fact of interest was, that all of the American species tested had proved as efficient as their European relative. The cantharidin was found to be more abundant in the soft parts of the insects than in the hard exoskeletal parts. To test the efficiency of a given species, the insects were collected and killed by either exposure to the steam of hot vinegar or the fumes of chloroform, drying them in a warm room. They were then either simply powdered and made into a paste and applied to the skin, or by throwing the powder into chloroform and after a time filtering or straining off the fluid and allowing evaporation to take place spontaneously, the cantharidin would then be found deposited. In 500 parts of the Chinese blister beetle, or *mylabris cichorii*, had been found 2.13 parts of cantharidin. According to our present classification *cantharis cinerea* of the dispensatory was known as *macrobasis unicolor*, and was found from Canada to Kansas, Georgia and Arizona; *cantharis marginata* as *epicanta cinerea*, found in the Middle States; *Cantharis atrata* as *epicanta pennsylvanica*, found in the Middle States to Texas; *cantharis albida*, as *macrobasis albida*, found abundantly in Texas. Some species were very abundant. *Cantharis Nuttalli* had been found on the plains of Missouri so abundantly as to be swept up by bushels; *cantharis vulnerata* of southern California was also found in great abundance.

#### Election of Officers.

The following officers were elected for the ensuing year: Dr. D. W. Montgomery, president; Dr. H. M. Sherman, vice-president; Dr. L. A. Kengla, secretary; Dr. H. Kreutzmann, treasurer.

### CHICAGO NEUROLOGICAL SOCIETY.

*Regular Meeting, held Dec. 19, 1901.*

Dr. Hugh T. Patrick, in the Chair.

#### Description of Curves Representing the Areas of White and Gray Matter in Human Spinal Cord at Level of Each Spinal Nerve.

DR. H. H. DONALDSON gave the description of a new chart drawn by Mr. Davis to represent the areas of the gray and white matter in the human spinal cord at the level of such spinal nerve. The base line represents the average length of the adult cord, and is divided into thirty-one parts, each having the length of the corresponding segment. The data for the areas of the cross-sections were taken from Stilling's tables. The new features in this chart are the division of the base line into lengths equal to those of the corresponding segments, and the use, for the areas of the cross-sections, of data derived from the measurement of the adult cord. The diagram at present found in the text-books is based on Stilling's measurements of the cord of a 5-year-old child, while the base line is divided into equal intervals for the segments, thus failing to give the measurements for the adult cord, and disturbing the relations of the curve which is presented.

#### Number and Size of Spinal Ganglion Cells and Dorsal Root Fibers in White Rats of Different Ages.

DR. DONALDSON next presented some results obtained by Mr. Hatai from his studies on the spinal ganglion of the white rat during the growing period. Four rats were used, their body weights being 10, 24, 63 and 167 grams respectively. In each rat the number of cells in the ganglion and the number of fibers in the dorsal nerve roots of the sixth cranial, fourth thoracic, and second lumbar was determined. On comparing these numbers thus obtained, it was possible to draw the following conclusions: 1. In the spinal ganglia the number of cell bodies is constant between birth and maturity. There is, of course, some individual variation in this number. 2. The fibers of the dorsal nerve roots are more than twice as numerous in the 167-gram rat as in the 10-gram rat, and the intermediate weights show intermediate numbers in the roots. 3. Since this is the case, it follows that the ratio between the number of cells in the ganglia, as compared with the number of fibers in the dorsal nerve roots, steadily decreases. In the

youngest stage, there may be as many as eleven cells in the ganglion for each fiber in the dorsal nerve root, while in the case of the most developed nerve there are still 2.7 cells for each fiber.

It appears that the new fibers are formed by the outgrowths of cells present in the ganglion from the earliest stage. Studies on the general activity of the rat show that they are most active when weighing from 25 to 35 grams, and therefore at a time when the number of fibers in the dorsal nerve roots is still very incomplete.

DR. HUGH T. PATRICK inquired, in discussion, whether a piece of foil cut out to correspond to the gray matter was used as the basis of measurement.

DR. H. H. DONALDSON said that the section was first enlarged about four times, the outline then drawn on tracing paper, which is placed over the foil, which is cut in accordance with the figure. From that figure the calculation is made. The foil used for this purpose must be of uniform thickness, so that the measurements will be accurate. The foil is sold in strips, and as the ends of the strip are much thinner than the middle piece, only the latter is used. These strips are all weighed so that they will correspond to the standard. The measurements can also be made with cardboard.

DR. HUGH T. PATRICK thought that this subject was of some practical importance in some of the degenerate diseases, especially cerebellar ataxia, in which the central nervous system has been found very small. He could not recollect any statement bearing on the small amount of white or gray matter, but simply recalled mention of the small size of the brain, the cerebellum, pons, medulla and cord. In one case, measurements of the cord were given in different diameters. He was of the opinion that in connection with some of the congenital diseases these comparative measurements might be of considerable interest.

DR. L. F. BARKER inquired as to the kinds of reproductions in Stilling's "Atlas."

DR. H. H. DONALDSON said they were lithographs, and were probably pretty accurate. The cross-sections of the cord were placed in cells filled with alcohol. The observations were made while the specimens were in a good state of preservation, before the alcohol had shrunken them.

DR. H. H. DONALDSON read a paper entitled

#### A Study of the Cells and Fibers in Different Segments of the Spinal Cord.

DR. L. F. BARKER regretted that Dr. Donaldson did not divulge his opinions based on the results of this work. Naturally a great many questions arise in connection with this work. He was especially interested in getting an explanation of the reason for the increase in the number of fibers. Three possible explanations suggest themselves. One, the growing-out of more fibers from the cells in the ganglion to the cord, probably the most likely explanation. The second possibility would be a division of single fibers already present, and the third an outgrowth of fibers from the cord to the ganglion, although that might be the least plausible.

The second point was the disappearance of so many of the small cells, the increase in the large cells, which apparently was due to the development of the small cells. Nevertheless, there are in all cases a large number of small cells left undeveloped. He said he would like to know whether these were surplus cells that never attained to maturity, remaining small cells without any processes, or whether they possibly can be cells which send out axis cylinders to end in cell bodies of other neurons. If they remain immature, it would be in accord with what is believed to occur elsewhere in the nervous system, namely, that in all parts of the nervous system, as in most parts of the body, there are cells left in an immature state capable of further development under certain circumstances. If that is the case, there are as many reserve cells in the ganglia as there are cells in the commission. That would be a very large excess in proportion to reserve cells, but if it is remembered that as in the *substantia gelatinosa* many cells develop and degenerate, as many as attain maturity, the excess would not seem so great. He also asked for the reason of the increase in the ratio of fibers to

cells, especially in the cervical region. Naturally the first thing to which attention would be directed is the possibility of the enormous development of the hand as a sense organ as compared with the thoracic region, and the lower extremity as a sense organ. He did not know whether in the rat the hand was more of a sense organ than the foot. In the human we might naturally expect a greater number of root fibers in the cervical roots than in the thoracic or lumbar. The hand area in the cerebral cortex is very large compared with the trunk or foot area. Another point, that this change in proportion takes place during the point of greatest activity of the animal, is extremely interesting, and suggests the possibility of a relationship between activity and development. It is a well-known fact that the exposure to strong light of prematurely born cats increases the rapidity of development of the myelin sheath. Why could it not be possible that the further activity should determine this rapid change in the ratio of fibers to cells? He hoped that Dr. Donaldson would explain these points.

DR. DONALDSON said that we might account for the increase in the number of fibers in the dorsal nerve root by assuming that the new dorsal root fibers grow out from cells which entered into commission in the later stage of the ganglion, being immature in the early stage. That explanation receives its best support from the relation in the cervical region between the large cells and the number of fibers. In the dorsal nerve root the number of large cells is equal to the number of nerve fibers. The division of fibers does not appear so probable in the sense in which it would have to take place, although many of the fibers are divided. These divided fibers all pass to the periphery, but such a division has always been observed at a stated place, the dividing branches being of equal length and equal growth, and not simply representing a series of twigs which might run out and thus add to the number of fibers. If these run out together, they would be counted at the same time, and would not account for the change in the condition in this period and some period where there were more dorsal nerve roots. All the evidence tends to point toward the throwing into commission of new cells for the addition of new fibers to the dorsal nerve root.

The question as to the excessive number of cells in the spinal ganglia, he deemed difficult to answer. One author found most of the nerve cells in the spinal ganglia to be of this type (indicating). There were a few cells, the axones of which ended within the limits of the spinal ganglion itself. These, however, are few in number, and can not account for the very large apparent excess of the cells in the ganglia. The excess will probably be found to be due to the immature cells which have not yet sent their axones out any great distance. The higher one goes in the nervous system, the greater appears to be the excess of cells found in the different localities. In man the excess is probably much greater than in the frog or rat. That is a rather dangerous thing to say, he said, because it is in the nature of a prophecy. However, it does not appear to be impracticable. It is rather difficult to say what these cells can be doing and yet there appear to be many of them in the cortex and there is no reason why they should not appear in the spinal ganglia. It seems to be a property of the nervous system to contain more parts than it actually needs and lives up to.

As to the difference between the number of fibers and the number of cells in the thoracic and lumbar regions as compared with the cervical region, he believed that possibly the sympathetic nerves have something to do with this. He said his first impulse was to associate the excessive number of cells in the thoracic region with the sympathetic connection which is absent in the cervical. This, however, is but a poor explanation, as it is open to question.

DR. HUGH T. PATRICK inquired whether the fibers in the brain had ever been counted; whether there is a tremendous increase in the fibers with the mental and intellectual development of the individual, or whether they simply take on sheaths; whether the corpus callosum at birth contains more fibers than in the adult.

DR. DONALDSON said that he had found the fibers present, but they did not have any medullary sheaths. The cell bodies

might be present, he said, but not their axones. He felt that the axones are a later growth in a large number of the cell elements. These observations have been made only from the standpoint of medullation, showing the increase in medullation as maturity is reached. He was positive that the axones are not present in rats. The rat's cerebrum can be cut very deeply and a few weeks later it is impossible to find the scar. The wound grows over completely, because the brain is cut at a time when most cell elements are in a neuroblast stage. There are no axones. For that reason it is difficult to find the place of injury.

DR. J. W. ENGBERT said that from comparative anatomy and biology it has been ascertained that the cord at one time had different segments which seemed to be more or less similar. In man it is found that certain segments gain a great deal, as, for instance, the cervical and lumbar, whereas the thoracic loses. In what does the gain consist? Do the segments gain chiefly in cell bodies, or do they send out fibers?

DR. DONALDSON said that in the gray substance where it is voluminous, there is an excessive number of cells. There is also an excessive number of fibers as is shown by the rise in the curve in the white substance coincident with the enlargement of the gray. The white substance is distributed both around the gray matter and within it. In the lumbar region the gray matter is comparatively less than in the cervical enlargement, and in that sense the smallness of this segment is really a reduction in the amount of white matter in it. It is accomplished by change in the shape of the cells. They lie like watermelons, on end, in the thoracic region; on their side in the cervical, and in the lumbar region as if they were sat on on their side, with the widest plane in the plane of this section. They have different shapes, according to the segments in which they are located. Though the segments are short in the lumbar region, the amount of gray matter is as large as in the cervical segment.

DR. L. F. BARKER advanced the supposition that if the base line were made so that the segment distances were equal, how, then, would the gray matter lie?

DR. DONALDSON said that the vertical length would have to be multiplied by the horizontal length, and the difference in the area exaggerated by making the segments equal. There is a relative increase of gray matter in the two enlargements when reduced to cubic contents.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### PRESCRIPTION WRITING, XV.

(Continued from page 531.)

#### Estimating Size of Dose for Children.

There have been several rules introduced for estimating the size of the dose, but the one generally employed is Young's rule, as follows: The adult dose is taken as the unit, and the child's dose indicated by a fraction having the age as numerator, and the age plus 12 as denominator. For illustration, in prescribing for a child 6 years of age the following formula will explain how the size of the dose can be ascertained:

$$\frac{6}{6+12} = \frac{6}{18} \text{ or } \frac{1}{3}$$

Therefore a child of 6 years should be given a dose equal to one-third the size of an adult dose.

Some one has recommended the following plan for prescribing quickly and accurately for infants under one year of age: In a 3-ounce mixture, when a teaspoonful is given at a dose, direct the druggist to put into the mixture as much of each ingredient as may be given to an adult at one dose. The following prescription will serve to elucidate the rule:

|                                  |    |
|----------------------------------|----|
| R. Tinet. nucis vom.....m. x     | 66 |
| Sodii bicarb. ....gr. x          | 66 |
| Aq. aurantii .....m. x           | 66 |
| Tinet. eard. comp. q. s. ad..... | 90 |

M. Sig.: Take one teaspoonful three or four times a day in water.

It will be seen by the above illustration that the amount of each preparation is approximately a single dose for an adult. In short, the infant receives one-twenty-fourth the adult dose, which is a safe calculation. In children between the ages of 2 and 4 years the size may be increased so that the amount of each ingredient in a 3-ounce mixture may equal two or three times the adult dose.

Cowling's method is somewhat similar to the above. His rule is to divide the age next birthday by 24; consequently for a child of 6 years the following formula would apply:  $6/24 = 1/4$ , or one-fourth the adult dose. The fault with this rule is that under ordinary circumstances the dose would be too small. Some physicians find 20 a convenient and safe denominator. Occasionally a rule is followed, based on the weight of the child, which is taken as the numerator of a fraction whose denominator is 140; this is supposed to be the average weight of an adult.

In prescribing for children as well as old people, exceptions arise in using certain drugs, as has been previously mentioned.

#### Metrical System.

The metric system is certainly being employed more and more each year and every physician should acquaint himself with this method. It has the advantages over the apothecary system in that it is exclusively used in nearly all civilized countries, and, when once learned, mathematical calculations are more easily made, as it is based on the decimal system. In order to convert the apothecary system into the metric system and vice versa, the following tables of approximate weights and measures should be memorized:

TABLE OF WEIGHTS.

|                      |             |
|----------------------|-------------|
| 1 grain .....        | .065 gram.  |
| 15.43 grains .....   | 1 gram.     |
| 1 dram (troy) .....  | 3.90 grams. |
| 1 ounce (troy) ..... | 31 grams.   |

TABLE OF CAPACITY.

|                     |           |
|---------------------|-----------|
| 1 minim .....       | .061 c.c. |
| 16 minims .....     | 1 c.c.    |
| 1 fluid dram .....  | 3.75 c.c. |
| 1 fluid ounce ..... | 30 c.c.   |

Thus, to convert grains or a fraction of a grain into the corresponding quantity in the metric system, multiply the number of grains by .065, and to convert the quantities written in the metric system into their equivalents in grains, divide by .065.

To convert drams into grams, multiply the number of drams by 3.75, and to convert grams into drams divide the number by 3.75, or less approximately and more conveniently by 4. The same rule is to be observed in dealing with ounces. But in converting minims, as observed in the second table, into the metric system the number of minims must be multiplied by .061 c.c., the number of fluid drams must be multiplied by 3.75 c.c., and the number of ounces by 30 c.c.

(To be continued.)

#### To Promote Elimination in Scarlet Fever.

The following is recommended by *Med. Standard* to increase the elimination and as a febrifuge in scarlet fever:

|                         |         |     |
|-------------------------|---------|-----|
| R. Tinet. aconiti ..... | m. viii | 50  |
| Potassii citratis ..... | 3iii    | 11  |
| Syrupi limonis .....    | 3ss     | 15  |
| Aque q. s. ad .....     | 3iv     | 120 |

M. Sig.: One teaspoonful every hour or two.

And as a gargle for the throat in scarlet fever the following:

|                            |       |     |
|----------------------------|-------|-----|
| R. Acidi carbolici .....   | 3ss   | 1   |
| Glycerini .....            | 3i    | 30  |
| Aq. camphoræ .....         | 3i    | 30  |
| Pot. chloratis .....       | gr. x | 66  |
| Aq. destil. q. s. ad ..... | 3vi   | 180 |

M. Sig.: Use as gargle or spray.

#### Treatment of Subacute Vesicular Eczema.

Dr. Jay F. Schamberg recommends the following as an excellent application in the subacute form of eczema:

|                                    |        |
|------------------------------------|--------|
| R. Acidi carbol. ....gr. x         | 66     |
| Hydrarg. chloridi mitis.....gr. xx | 1 30   |
| Pulv. amyli .....                  |        |
| Pulv. zinci oxidi, āā.....3ii      | 7 50   |
| Petrolati .....                    | 3ss 15 |

M. Sig.: Apply locally once or twice a day.

This paste is valuable in all forms of eczema except the very acute forms. He recommends the following as a valuable anti-pruritic and cooling ointment in the different forms of eczema:

|                       |          |        |
|-----------------------|----------|--------|
| R. Menthol .....      | gr. v-x  | 33-66  |
| Acidi carbolici ..... | gr. x-xx | 66-133 |
| Ung. aquæ rosæ .....  | 3i       | 31     |

M. Sig.: Apply locally to the itching surface.

#### Guaiacol Inunctions in Tuberculosis of Childhood.

Dr. Rachford, in *Archives of Pediatrics*, has derived very satisfactory results from the use of the following ointment in treatment of tuberculosis of children:

|                   |     |       |
|-------------------|-----|-------|
| R. Guaiacol ..... | 3i  | 3 75  |
| Lanolini .....    | 3ii | 7 50  |
| Adipis .....      | 3v  | 18 75 |

M. Sig.: One level teaspoonful to be applied to the chest at bedtime each day and well rubbed in.

#### To Abort Attacks of Coryza.

|                            |            |
|----------------------------|------------|
| R. Acidi carbol. ....m. xv | 1          |
| Aq. ammoniæ .....          | m. xx 1 33 |
| Alcoholis .....            | 3i 3 75    |
| Aq. destil. ....           | 3ii 7 50   |

M. Sig.: Five or ten drops to be placed on blotting paper and the vapor inhaled for a few times every two hours; or:

|                                  |          |
|----------------------------------|----------|
| R. Cocainæ hydrochlor. ....gr. x | 66       |
| Menthol .....                    | gr. v 33 |
| Salol .....                      | 3ii 7 50 |
| Acidi borici .....               | 3i 31    |

M. Sig.: To use as an insufflation four or five times a day.

#### Treatment of Hemorrhoids.

The following is recommended as a local application in treatment of hemorrhoids:

|                               |          |
|-------------------------------|----------|
| R. Morphina sulph. ....gr. ii | 13       |
| Olei olivæ .....              | 3ii 7 50 |
| Ung. zinci oxidi .....        | 3i 30    |
| Pulv. gallæ (nutgall) .....   | 3ii 7 50 |

M. Sig.: Cleanse the parts thoroughly and apply locally once or twice daily; or:

|                        |             |
|------------------------|-------------|
| R. Acidi gallici ..... | gr. xx 1 33 |
| Ext. opii .....        | gr. x 66    |
| Ext. belladonnæ .....  | gr. x 66    |
| Ung. simplicis .....   | 3i 30       |

M. Sig.: Apply locally to the painful parts.

#### Treatment of Granular Lids.

J. G. Huizinga, in *Amer. Med.*, mentions two classes or stages. In the first or catarrhal stage, the symptoms are those of an aggravated conjunctivitis and the granulations are not visible. Ice or the artificial leech is applied locally to reduce the congestion. He recommends the following to be instilled every hour:

|                                |       |
|--------------------------------|-------|
| R. Acidi borici .....          |       |
| Sodii biberatis, āā.....gr. xx | 1 33  |
| Aq. camphoræ .....             |       |
| Aq. destil. āā.....            | 3i 30 |

M. Sig.: A few drops into the eye every hour or two.

He also recommends that an application of tannic acid, boroglycerid, silver nitrate or protargol to the everted lid be applied once a day; an ointment of ichthyol 1 to 5 per cent. strength may be applied at night. In the second stage the secretion becomes muco-purulent and well-marked granulations are present. Often there is pannus due to irritation of the cornea. For this stage the same treatment is indicated as already outlined, except that hot applications are preferred. The follicles should be evacuated with a suitable forceps. After removal, the surface should be mopped with a bichlorid solution, 1 to 1000, followed by a boric acid douche. Excision of the redundant folds has been practiced and may be effective in

cases which resist other treatment. He favors metallic electrolysis. After cocaineization the lid is everted and a constant current of five milliamperes used for five minutes with a copper or silver electrode. The deposited metal is believed by the author to be antiseptic. This operation may be repeated once or twice a week and is supplemented by a protargol solution 25 per cent. strength and boric acid washes.

### Medicolegal.

**Injury to the Eye.**—The Appellate Court of Indiana holds, in *Van Camp Hardware & Iron Company vs. O'Brien*, that where a girl not quite 9 years old had her left eye injured by another's negligence, the eyeball being cut open, causing her to suffer pain and lose the sight of the eye, an award of \$2500 damages could not be considered so excessive as to warrant a judgment therefor being disturbed.

**Expert Evidence and Testamentary Capacity.**—The Supreme Court of Iowa holds, in the case of *Marshall vs. Hanby*, that it is not for a witness, though an expert, to say what will constitute capacity. That is a question of law for the court, and when advised the jurors are to say whether, in view of all the evidence, it was possessed by the deceased at the time the will was signed. The opinion of the expert must be limited to the estimate of the mental condition of the person concerning whom inquiry is made, and never allowed to be given as to the effect of that condition upon the particular transaction being investigated.

**Court Not Entitled to Introduce Medical Witnesses.**—In a personal injury case against a street railway company the latter moved to require the party suing to submit to an examination by two physicians, named in the motion, for the purpose of ascertaining the character and extent of her injuries, and in order that the physicians might testify with reference thereto upon the trial of the case. This motion, on objection by the party suing, was overruled, but the trial judge offered to require her to submit to an examination by two doctors to be appointed by him, and the company filed a motion to that effect. The judge then named two physicians to make the examination, and the case went to trial. Later, and before the examination was made, the company withdrew its motion. On the following day the judge called one of the physicians, over the objection of the company, and asked him a number of questions, after which counsel for the party suing continued the examination. Then the judge called the other physician, over the objection of the company, and required the parties to examine him, over the objection of both parties. Now the Court of Appeals of Kentucky does not consider it necessary, in reviewing the case, *South Covington & Cincinnati Street Railway Company vs. Stroh*, to decide what might have been done had the examination been made before the withdrawal of the motion. But the examination having been made after the withdrawal of the motion, it thinks that it was clearly erroneous to introduce the physicians as witnesses in the manner in which it was done. It says that they were presumably disinterested, and the fact of their introduction by the court against the earnest protest of the defense tended to give undue weight and prominence to their testimony, in so far as it supported the contention of the party suing.

**Taking Injured Person to Hospital Against His Will.**—The Supreme Court of Pennsylvania makes use of the opinion of the lower court, in deciding the case of *Ollet vs. the Pittsburgh, Cincinnati, Chicago & St. Louis Railway Company*. Here a boy 17 years of age, while endeavoring to climb upon a freight train fell from it, having the front part of his foot crushed under the wheels. He was immediately taken to a private house, the only one in the neighborhood. Then the crew of the train, having run to a town one or two miles distant, returned with the engine, and finding the boy in the house, and no one present except a young woman who lived there, took him on the engine to the town, where the company's physician was in attendance, and where an uncle of the boy was also at the station when he was brought there. Thence, upon the advice of the company's doctor, and accom-

panied by the uncle, he was taken to a hospital, where his foot was afterwards amputated. But at the time of the accident one or more other boys were present, and one of them went to the town to call the family physician of the boy's father, and another went to the house of the boy's father to call him. In consequence, when the crew of the train got back to the house, on the return thereto above mentioned, they were told by the boy that his family physician had been sent for, and that he did not want to go to the hospital, but they insisted that he should; carried him out; put him on the tender of the engine. This removal of the boy from the house by the railroad to the town, and thence to the hospital, was made the basis of an action for false imprisonment. That the crew of the train, in doing what they did, were endeavoring to act the part of the Good Samaritan, the court said, was perfectly plain, and it did not see how a jury could be allowed to find otherwise from the evidence. The circumstances certainly seemed to call for great haste, and one who endeavors to assist his neighbor who is in great danger and distress is certainly not liable for a mistake in judgment, nor did there appear to have been any such mistake in this case. In addition, the court said that it did not see how the railroad company could be held liable for a false imprisonment on these acts of its employees, which were certainly not done within the scope of their employment, which was that of a crew of a freight train. On this opinion, the Supreme Court holds that the court below properly refused to take off a non-suit.

### Skill and Contributory Negligence in Malpractice Case.

—The Supreme Court of Iowa holds, in the malpractice case of *Decatur vs. Simpson*, that locality is material, in determining the skill required of a physician. Here, the physician asked that the jury be instructed that, "The implied contract of the defendant when he assumed charge of the treatment of plaintiff's injuries was that he possessed and would employ in the treatment of the case such reasonable skill and diligence as were ordinarily exercised in his profession at and in localities similar to that in which he practiced, by the members as a body; that is, the average of the reasonable skill and diligence ordinarily exercised by the profession at the time and in places similar to G—. Regard is to be had, in determining this ordinary skill and diligence, to the improvements and advanced state of the profession at the time the case was treated." That this instruction announced the correct rule was conceded. And the court holds that it was not sufficient to give one similar in terms, except that it ignored locality. It also holds that in an action for malpractice, based on alleged negligence, in which the relation of the parties is material only as fixing the degree of care required, the party suing must negative contributory negligence. It says that there are many and respectable authorities to the contrary, but that it seems irrevocably committed to the doctrine, and has generally applied it in all cases where a party seeks to recover for the negligent or unskillful acts of another. Indeed, it says that the only exception it has recognized seems to be in cases where the owner of stock is seeking to recover for the unskillful acts of a veterinary surgeon. So, the party suing in this case having failed to show that he was not guilty of contributory negligence, the court holds that his petition did not state a cause of action, and was subject to demurrer, or the same question could be raised by motion in arrest of judgment. Nor does it consider that the overruling of such a motion was without prejudice by reason of the fact that the issue was submitted to the jury under an instruction that the burden was on the party suing to show freedom from contributory negligence. It says that the physician was compelled to first introduce his evidence regarding contributory negligence, and, of necessity, was limited to such acts and conduct of the party suing (the patient) as came to his knowledge. Under this order of procedure, all that the party suing needed to do was to negative these particular facts. That done, his case was made out, without showing his freedom from negligence generally. Manifestly, this was to the disadvantage of the physician, even though it be conceded the jury was properly instructed with reference to the matter.

3. Vesico-Vaginal Fistula.—The new operation described by Smith consists in the following procedures: 1. The vagina was incised across and in front of the cervix, pushing the bladder off from the uterus in the same way as in the first step of vaginal hysterectomy. The cervical laceration which extended up the internal os was operated on by the Emmet method. "2. The vagina was separated easily from the bladder with the finger everywhere except where the two torn edges had become united by fistula. With the finger between the vagina and the bladder it was quite easy, by a few cuts with the scissors, to separate them from one end of the fistula to the other. As this cut gave a raw edge there was no need of cutting away a single particle of either. 3. The long tear in the bladder was now caught with a catgut stitch at either end, only taking in the muscular wall and held on the stretch by an assistant. It was only the work of a minute or two to bring the muscular wall together with an over-and-over fine chromicized catgut suture going back fully an eighth of an inch on each side, but taking care never once to penetrate the cavity of the bladder or even to touch the mucous membrane. When this was finished there was a strong ridge on the site of the tear, nearly one-fourth of an inch wide, which was tested with sterilized milk injected into the bladder from a fountain four feet above it, giving quite a pressure and not a drop came through. 4. The slit in the vagina was closed with interrupted silkworm gut passed through the vagina, then through the muscular wall of the bladder but half an inch to the right of the tear in the bladder, and then through the other side of the vagina, thus displacing the bladder half an inch to the patient's left, so that the line of suturing in the two membranes was no longer in the same place as the line of the tear was. By this means the line of suture of the bladder was backed up or strengthened in front by half an inch of solid vagina instead of a line of sutures, and should any pressure be accidentally brought to bear upon the sutures in the bladder, it would have to overcome a valve instead of a hole, and the harder it pressed the tighter did the valve close." The catheter was left in for five days, after which the patient passed water naturally three or four times a day, and has had no trouble since. He lays special stress on three or four points, one is that by adopting this method we avoid leaving any stitches in the bladder mucous membrane, where they are liable to become the nuclei of most troublesome calculi. Stitching of the mucous membrane is quite unnecessary because the edges are brought together by the drawing together of muscular layer immediately underneath it. Instead of depending on the union of a narrow edge, about one thirty-second of an inch thick, we obtain a thick ridge fully an eighth of an inch thick in the bladder alone, to say nothing of the vagina against it. He emphasizes the great importance of leaving in a *catheter à demeure*, which should be used in every case in which anything has been done to the bladder wall, as it removes all tension and places the bladder at complete rest so long as it remains in. He thinks there is no longer any need of a woman dragging out a wretched exist-

ence when we have at our disposal such an easy and certain method of closing the very worst vesico-vaginal fistula.

**4. Septic Poisoning and Accident Insurance.**—Kemper gives his experience with accident insurance companies as regards this disability and goes over the policies of different companies in regard to this point. He thinks the following propositions may be declared: 1. The surgeon who is insured and receives a disabling wound unfitting him for practicing his profession, is entitled to an indemnity whether he contracts septic poisoning or not. 2. A surgeon, while operating, may become infected through an old injury, or a new wound. The effects are the same in either instance. There is no valid reason why a policy should not indemnify alike in both cases. 3. If a surgeon can not recover indemnity from an infection received through a sore, or an abrasion, then he gains nothing from a clause or rider attached to his general policy. In other words, the term "septic poisoning" in an accident policy is simply an aid to secure policy holders!

**7. Brain Tumors.**—Collins' article is largely casuistic; he reports five cases of brain tumor showing certain points of interest. One of these was a tumor of the pons with the symptom of unilateral ataxia, extending from the beginning of the illness to the end, an extremely rare accompaniment. It is credited by him to lesion of certain fibers of the fillet, the central sensory pathway. There was also absence of choked discs, of degeneration reaction in the right seventh nerve and of pressure symptoms. The sense of hearing was also unaffected. Another was a case of syphiloma with nuclear symptoms and diagnosed as a tumor of the pons, but found in the anterior portion of the left hemisphere. The third case was a rare instance of cerebellar sarcoma, in a child.

**8. Latent and Masked Malaria.**—Craig gives an analysis of 195 cases treated at the Presidio Hospital in returned soldiers from the tropics. Of these, 44 were tertian, 1 quartan and 150 estivo-autumnal infection. The clinical diagnosis before the blood examination in the majority of cases was chronic dysentery or diarrhea. In 14 cases pulmonary tuberculosis was diagnosed. Other ailments and derangements were clinically diagnosed in one or two cases each. He thinks that the occurrence of masked malaria in cases coming from the tropics is a matter of the greatest importance and in dysentery cases the marked debility that exists is often due to this complication. There is also evidence of the estivo-autumnal form originating in San Francisco. From an analysis of these cases he calls attention to the danger produced by malarial infection complicating any disease and to the good effects of elimination of this element.

**11. Surgery of the Pancreas.**—Park comprehensively reviews the surgical possibilities of the pancreas, noting the injuries that may occur and routes and methods in which the organ may be reached. In acute traumatism the indications are, to check the bleeding, to prevent escape of pancreatic juice, to suture, etc., to disinfect the cavity, and to repair the balance of the injury. The fatality of such traumatism is not easily ascertained. At least four cases of men injured during the Civil war lived for a period after their injuries and died from complications, and how many others had the viscus injured and completely recovered may never be known. There has been no case of complete removal of the pancreas in the human subject, but a great portion of it has been and can be spared and nearly all of a prolapsed pancreas has been removed. In a few cases prolapse of the pancreas has been noted and certain portions have been removed from such cases or the prolapse has been reduced. For malignant tumors of the head of the pancreas there is probably no hope, but in localized abscesses or tumors of the splenic portion excision of the splenic end has been successfully practiced and is as justifiable as removal of this part for gangrene. Pancreatic cysts have been thoroughly dealt with by Senn and others, and their surgery more fully discussed than some other lesions. Park remarks that operation is often difficult from adhesions and these of such strength that injury to other organs may occur from breaking them up. The cyst may be exposed and tapped and a portion

of the redundant part cut away, the remainder sewed to the abdominal wall and drainage provided for with a large tube. In a few cases the cysts have been pedunculated and, therefore, could be extirpated. The surgeon should be prepared to find more or less of the true pancreatic tissue stretched over such a peduncle, and if it can be done it would probably be better to peel this pancreatic tissue back before ligating the peduncle. The amount of discharge is enormous in these cavities, but where radical measures are impossible, drainage usually is followed by slow contraction and final healing, and where possible it is desirable to explore for calculus. Some pancreatic cysts are the result of obstruction of the duct of Wirsung, and removal of such calculi, if they can be detected, should certainly be made part of the operative procedure. If the calculus can be found it should be removed by excision. Whether this be done through the texture of the gland, or through the extremity of the duct, or through the duodenum, depends on the case. In some instances it has been possible to draw the stomach so far forward and outward as to bring the duodenum into the field sufficiently to justify opening it and going through it into the diverticulum of Vater, and one should be prepared to do this if necessary. Acute pancreatitis is discussed at some length. The cases of the severest type need early and prompt intervention. Those which go on to gangrene offer more hope to surgery. Park says an acute pancreatitis is characterized in the case in hand by fat necrosis, hemorrhage, pus or gangrene. In cases where the tumor can be felt in the left lumbar region, the entire operation can be done from the rear, and Park advises exploratory operation in most cases of acute pancreatitis with decided symptoms. There seems to be a connection between pancreatic disease and hemorrhage. The more acute the symptoms, Carnot claims, the greater the liability to hemorrhage and that it often follows grave traumatism as well as sometimes poisoning by mercury and other chemicals. The treatment of acute pancreatitis is virtually that of peritonitis of the upper abdominal cavity and consists very largely, as Fitz has suggested, in drainage. Early operation is just as wise as in fulminating appendicitis. Drainage is preferable posteriorly, though the initial operation is usually made anteriorly. In subacute pancreatitis, treatment consists for the most part in opening and of drainage of localized abscesses. In chronic pancreatitis the treatment consists in a large measure of attacks on the biliary passages, which for the most part are best approached by incision through the right rectus, or by Bevan's sigmoid incision, splitting the rectus as far as needed, the cut being several inches long. Most cases are produced by conditions having their origin in the biliary organs and involving the pancreas only secondarily. The cases of pancreatic calculus causing obstruction of Wirsung's duct, of course, are well known and probably more would be reported were observations and examinations more frequently made. Most of the cases are characterized by jaundice as well as enlargement of the liver and gall-bladder. Cipriani has emphasized the diagnostic importance of glycosuria as well as the presence of calculi in the feces. In some cases the difficulties would suggest the expediency of cholecystenterostomy, which may be the best way out of the trouble, especially when there is well-marked obstruction in the neighborhood of the diverticulum of Vater. The relief of tension afforded by draining the bile-ducts may indirectly drain the pancreatic ducts and lead to subsidence of the pancreatitis. Simulation of malignant disease by chronic interstitial enlargement, especially of the head of the pancreas, should not be a barrier to operation in cases in chronic jaundice where the health is failing, since much can be done so long as malignant disease is not present. The method of reaching the calculus is described. Pancreatic tuberculosis in most cases is probably due to extension from neighboring foci, primary tuberculosis being certainly rare.

**12. Tuberculous Peritonitis.**—Bottomley has studied the effects of operation on tuberculous peritonitis at the Boston City Hospital in 28 cases, which he tabulates. The immediate results are almost always improvement, at least in the general if not in the local condition. The remoter results are not so uniformly good, but he reports in the 28 cases 9 of recovery

ranging from fourteen months to five and one-half years of observation. Several cases are not traced and others report improvement for periods of several months. He summarizes as follows: 1. We may reasonably expect cures (*i. e.*, one year or more after operation) to follow the operation in from 30 to 40 per cent. of all cases. In fatal cases the patients usually die within a few months after operation. 2. Family history does not appear to be important etiologically. Previous inflammatory affections of the abdominal viscera may have etiologic significance. 3. Operation usually affords at least temporary improvement either locally or generally even in cases that later may prove fatal. The use of drainage following the operation should be avoided when possible. 4. Inferences as to the remote results of operation should be drawn very guardedly, if at all, from the immediate results; though in cases which do not immediately receive from an operation either local or general benefit, the prognosis is very unfavorable.

**13. The Inhibition of Muscular Contraction.**—The points attempted to be brought out by Spingarn in this essay are summarized as follows: 1. It is possible, by means of electric, mechanic, physical and chemic stimuli, to inhibit a condition of muscular contraction. 2. All motor nerves probably contain two sets of fibers, one excitatory and the other inhibitory—the excitatory ones ordinarily predominating in their effect on the muscles. 3. The function of the inhibitory fibers is to prevent an excessive manifestation of the energy of the muscle, when the latter has been aroused to contract; the inhibitory fibers bearing a relation to the muscle-machine somewhat like that of the “governor” to the steam engine.

**19. Faulty Uterine Growth.**—The condition here treated of by Craig is non-development of the uterus, which is often seen in young women from 15 to 17 years of age or who have recently passed the period of puberty. They have lived a sedentary and studious life, which almost invariably results in a sluggish metabolism and constipation, and are usually long and constant sleepers. The principal factor in the diagnosis is the uterine probe. If the body cavity equals or exceeds in depth that of the cervix a hopeful prognosis may be given, though both measurements are small, but if the cervical canal exceeds that of the body an unfavorable prognosis is the only one justified. Treatment must be both general and local, and it is usually best to withdraw such a patient from school or the sedentary occupation for about a year, and to require out-of-door life. Iron often has been useful, even in cases where it did not seem to be indicated. The local treatment employed by him has been the intracervical application of impure carbolic acid, negative galvanism, and faradism, and these have been supplemented by prescribing for the patient's home use very hot two-quart douches each night. Where this treatment has no direct result discission may be used and has proven almost invariably useful. There is some danger of increasing the retroversion tendency, and especially if the intra-uterine electrode be used, and if the sagging shut off the circulation the result is to stop the growth. He therefore has used pessaries to properly support the uterus from the start and he ordinarily employs a small soft or hard rubber retroversion pessary, with or without a bulb, according as the ovaries show a tendency to prolapse or not. The smallest pessary that will do the work should be used. If the patient is frequently seen there is no danger of its doing any harm. He requires the patient, as a rule, to wear it six months after the uterus becomes of normal depth and menstruation is regular. It is then removed tentatively and the patient seen once a week until after the next menstruation, to make sure that the ligaments are sufficiently strong. One caution seems specially noteworthy, and that is to see that the flows of blood are really catamenial and that the increase is actual growth and not merely swelling due to inflammatory reaction. Bleedings from the uterus accompanied by swellings are easily induced, but this is not what is desired.

20.—This article has appeared elsewhere. See *THE JOURNAL OF February*, §83, p. 480.

**22. Management of Cerebral Hemorrhage.**—Browning advises elderly persons and those giving evidence of senility to

avoid excessive strain as well as physical shocks, jars, brain-tire, and severe muscular exertion are included. Mild constipation, indigestion, rush of blood to the head, insomnia and prolonged worry must all be attended to. He gives illustrative cases showing how the attacks begin and the necessity of prompt and proper treatment. The first and main principle that he wishes to advocate is the use of powerful, quickly-acting muscular and vaso-depressants. Among these he ranks first gelsemium, then aconite and veratrum. He would start the fluid extract of gelsemium in 10-drop doses and continue with from 5 to 10 drops as indicated, or with gelsemin in doses of 1/10 to 1/8 of a grain and continuing in 1/20. Aconitin might be given at first in doses of 1/100 to 1/50 of a grain. The initial dose often needs to be large or else rapidly repeated until the physiologic effect is produced. If the cause be traumatic, the same principles hold good. He would absolutely immobilize the patient as far as possible, allowing no muscular exertion whatever and though purgatives may sometimes be needed it is not necessary to disturb the patient by their use. Phlebotomy is more than replaced by the depressants. The use of gelatin to prevent hemorrhage is mentioned, but its action is considered too slow to meet the emergency. The question whether it may be used as a prophylactic is suggested. For the headache that so frequently attends the attack, antipyrin and its allies in small doses do well, but the depressants are best for the restlessness. Sometimes a little bleeding would be good, and he suggests the methodical trial of nasal scarification in suitable cases. Where nephritis, syphilis or alcoholism exists we must remedy that factor as well as we can. Among the “don'ts” he says “don't give stimulants, don't resort to saline injections, don't use depressing diaphoretics, don't prescribe digitalis, don't resort to opiates, don't try the nitrites as their use in any form is here out of place, don't permit any muscular exertion on the part of the patient.” In the subacute stage, after about one week, during which the patient has been kept as quiet as possible, the rent may be assumed to be permanently obstructed and we may allow limited exercise. As the arterial tension demands it the vascular depressant should be kept up in smaller doses. The return to exercise should be gradual. In the chronic state he believes in cultivating whatever power remains and gives directions as to the exercises that are advisable.

**26. Pneumonia.**—Nammack is doubtful as to the value of the serum treatment and the most that can be said is that it does no harm. The increase of leucocytosis is a favorable symptom, but we should avoid anything that increases leucocytosis and also weakens the heart; therefore, pilocarpin, acetanilid, antipyrin and nuclein are not advisable. The patient should be kept in a cool, well-ventilated room. A bodily temperature under 104 F. requires no special antipyretic measures, since a moderate elevation of temperature may be welcomed as useful in the presence of infection. Temperature above 104 F. may require a compress of linen wrung out of water at 60 F. and applied around the chest; if associated with delirium an ice helmet can be ordered in addition. Snug bandaging will help the pain, cough or dyspnea, and Dover's powders will be a valuable adjuvant. When hepatization has occurred, his faith remains pinned to four things, strychnin, nitroglycerin, alcohol and oxygen. The first two will be sufficient in the moderately severe cases. His practice is to order 1/60 of a grain each of strychnia and nitroglycerin in a teaspoonful of wine of pepsin every two hours with six ounces of milk, and Apollinaris water two ounces, on the alternate hour, the cold water in the intervals *ad libitum*. If these remedies fail to hold the case and the pulse goes up to 120 then whisky is ordered in half-ounce doses frequently repeated, as better than in larger quantities at longer intervals. Nammack believes that alcohol has a triple use in pneumonia: It reduces temperature by evaporation and radiation; lessens the heat production and, most valuable of all, it supplies a fuel or food to be burned up instead of tissues. Its drawback is that it tends to produce relaxation of the peripheral capillaries and to favor stagnation in them, with damming back of the blood upon the right heart, which must be met by the conjoint admin-

istration of vasomotor stimulants, like strychnin. Regarding the use of oxygen in pneumonia, he gives no logical reason for its value, but admits that it is of use. It is possible that it is inimical to the germs. The author is in accord with Dr. Keefe in his statement that without primary venesection it is never safe or advisable to make any considerable addition to the circulating fluids at the acme of an acute disease like pneumonia. The chief cause of death in uncomplicated cases is degeneration of the myocardium, due to toxemia and mechanical obstruction. Our objects of treatment are to eliminate the poisons and sustain the heart, and since the lungs and usually the kidneys are crippled, our available avenues of elimination are the bowels and the skin. The familiar "five and fifteen" (calomel, 5 grains; sodium bicarbonate, 15 grains) followed by saline laxatives, and repeated judiciously during the progress of the case, will attend to the gastro-intestinal system. The skin may be acted upon by water—cold, tepid or hot—each according to its special indications. The peripheral circulation or resistance are kept up by the vasomotor stimulants, strychnin, alcohol, and nitroglycerin. Local treatment is often expected by friends in private cases and it is cruel and unnecessary to disappoint them altogether, but it is more cruel and unnecessary to blister, poultice and bake a patient's thorax. He calls attention to the danger of pneumonia spreading to other members of the family, especially when they are in close attendance on the patient. The disinfection of pneumonia sputum and disinfection of the house in which several cases have occurred in rapid succession is suggested by Osler. He does not wish to have it understood that he follows any routine treatment by this mention of four principal remedies. It is the patient with pneumonia, and not the pneumonia that he treats. "Drugs are of no use unless mixed with brains."

31. **Heredity.**—This article, as stated in a footnote, is an expansion of the paper read before the American Medical Association and published in THE JOURNAL of February 8, p. 388.

32.—See abstract in THE JOURNAL, xxxvii, p. 1730.

34.—This article covers the same analysis of cases as the one which was abstracted in THE JOURNAL of February 15, 1920, p. 479.

35. **Retinal Lesions and Bright's Disease.**—Jackson describes the retinal conditions in Bright's disease, including the alterations in the contour, size and color of retinal vessels, especially the alteration in the color of the optic disc, a dirty brick-red discoloration which is one of the earliest and perhaps the most constant ophthalmoscopic symptoms. It belongs to the stage of high arterial tension and may antedate any notable change in the urine. It is not well described in the usual account given to ocular lesions, but the author has observed it often and mentions it with no question as to its significance. The irregularity in the caliber of the vessels, the alterations of outline of the arteries, which may be set down with certainty as abnormal, notable contractions and considerable lengths of broadened vessels are more frequent than distinctly sacculated aneurysmal dilatations, though these latter do occur. Alterations in the contour of the veins are much more common and can be made out in practically all cases. The changes in the size of the vessels really include the foregoing conditions. The tortuosity of the retinal vessels is chiefly a sign of dilatation. It may be marked in a single vessel, but more frequently affects all. Pathologic tortuosity shows great variations of depth of the different parts of the vessels. The curves are toward and from the center of the eyeball as well as in the plane of the retina, but the most frequent guide to the character is the co-existence of other retinal lesions, particularly the irregular venous dilatations. He also notices changes in the color, darker in dilatation and paleness from anemia and changes due to opacity of the vessels, which are often yellowish from such causes. A rare but most striking condition is an opaque brilliant white color due to fatty degeneration which is usually confined to a single vessel or in limited patches, though it may be quite general as in one case observed. Retinal hemorrhage is pretty constant, but there are times when it can not be found. Usually the hemorrhage spreads in the nerve fiber layer to

give it the usual flame shape, but smaller rounded dots of effused blood are frequent, and may be overlooked. Very large hemorrhages are rare in this condition. They are more apt to attend the toxic exudative form. How long any particular retinal hemorrhage will be recognizable is always uncertain. Small ones may be apparently unchanged for a considerable period and larger ones may rapidly disappear. Rapid and complete disappearance is probably a favorable sign. All these symptoms are dependent upon alteration of the vessel walls and are the retinal expression of the general vascular degeneration, which is essentially a part of the disease. The edema and degenerative changes are so constantly associated with these that it is reasonable to suppose they have the same origin. Edema is usually localized or more permanent in certain parts than others. The brilliant white patches due to fatty degeneration are the most striking ophthalmoscopic appearances of chronic interstitial nephritis and probably always appear in cases that run the complete course. They may be the result of retinal hemorrhage, the late stage in the history of a mass of exudate or follow localized edema, but smaller patches may arise without any evident preceding lesion and seem to have a direct relation with the underlying vascular change or its cause. These may be found at the very first examination of the case, but are usually of later appearance. The masses of exudates cause swelling and dirty reddish-white blotches of the fundus which undergo great changes and may sometimes entirely disappear. The large majority of patients who present these lesions die within a year or two. In conclusion he says: "Whether the vascular changes cause the retinal lesions, or whether their connection is that both spring from a common cause, the retinal symptoms take from this close connection great importance. They throw light upon what goes on in the central nervous system, and modified *pari passu*, in other organs of the body. Whether considered as a means of understanding the essential nature of this disease process, or as throwing light on the character and course of the individual case, they have an importance that the mass of physicians very imperfectly appreciate."

38. **Hemorrhoids.**—The two operations here described by Ingalls are the Thompson modification of the Whitehead operation and the Keiller method, which consists in dissecting under the mucous membrane for about an inch above the anus and depriving it of its veins and connective tissue. It is then re-sutured, using a padding or plug of iodoform and gauze in the rectum with central drainage tube, and removing it in twenty-four hours. He thinks this last operation deserves first place among recognized procedures for the relief of this very troublesome condition. The chief points of superiority are: 1, No danger of stricture; 2, no possibility of recurrence, all venous radicles being removed; 3, the least danger of infection; 4, no blood clot in the peri-anal space; 5, the greater comfort of the patient.

42. **The Action of Heat on Cow's Milk.**—Dessau claims that the action of heat on cow's milk when exposed for ten minutes to a gradual rise to from 140 F. to 160 F. does not coagulate the albumins and nucleins, neither does it decompose the fats nor render the calcium salts insoluble. It does, however, destroy or inhibit the growth of 99 per cent. of the vegetating germs in the milk and it does modify and alter the curdling of the caseinogen to the extent of approaching nearer to that of the curd of human milk. This action of heat upon the digestibility of casein is increased by dilution with plain water and possibly also by gruels made from cereals. While his ideas are not exactly in accord with the present theories of imitating human milk on a so-called scientific basis and as the observations on the digestibility of heated cow's milk do not entirely agree with those of other authorities, he claims that it is submitted on the basis of careful observation and not on any mere theory or laboratory results. His experience enables him to make the emphatic assertion that cow's milk prepared in this way by heating will not only make infants thrive when given as a daily food, but that the same results were obtained in numerous instances where other artificial foods, including home modification or percentage feeding, had previously markedly failed.

**55. Diabetes.**—Flexner states the limits of our knowledge concerning pancreatic diabetes and mentions the evidences of other forms. He thinks it probable that diabetes can also result from disease of the liver, but the theory is less satisfactory. The notion that the pancreas regulates the carbohydrate metabolism seems to be most in favor, though he points out that it is purely hypothetical. It is largely supported by analogy with other glands, such as the thyroid and adrenal. Thus far the number of theories advanced fail to explain all the phenomena, but it seems to be demonstrated beyond doubt that diabetes results from failure of a special internal function of the pancreas and that it is not due to nervous lesions or the absence of the digestive secretion of the organ. That pathologic conditions of the central nervous system and perhaps of the sympathetic system and larger peripheral nerves may give rise to glycosuria and diabetes is, of course, established, but there is no evidence to show that such exert a direct influence on carbohydrate metabolism and thus produce the condition. What this relationship between the central nervous system and the organs of carbohydrate metabolism is we are not informed, but the influence of this secondary organ is maintained by the author. The occurrence of renal forms of diabetes, he holds, is still unproven. Glycosuria and diabetes are not the same thing and a distinction is made between them. Glycosuria follows so many and different pathologic conditions that its significance is comparatively minimal. It may be rapid in appearance and just as rapid in disappearance. The organs that appear to preside over carbohydrate metabolism are the pancreas and liver, but their mechanism has not yet been solved.

**57. Lead Poisoning.**—McCarthy reports experiments on lead poisoning in dogs with brain examinations, showing a progressive degeneration with disappearance of the ganglion cells, followed by an increase in the glial elements associated with a very remarkable non-inflammatory endarteritis and periarteritis. The reaction of the tissues in this case to an invading toxic irritant are very marked, and associated with the capillary hemorrhages would, in that sense, constitute an inflammatory process, but he prefers not to use this term in the absence of round-cell infiltrate other than that of proliferation of the glial nuclei. The same process occurring in a human being could give all the symptoms, including the convulsions, of a case of paresis, and it can be easily understood how some cases present a clinical picture of that disease.

**58. Ovarian Transplantation.**—The history of ovarian transplantation is reviewed by Nicholson, who sums up the results of the work reported to date. It may be first stated that transplantation of the ovaries, either homo- or heteroplastically, is possible and that pregnancy will follow in a small proportion of cases. Further, it may be authoritatively stated that there is without doubt an influence inherent in the ovaries beyond the mere process of ovulation which is very important for the development of the genitalia and also for their conservation. Whether this is strictly an internal secretion or not remains to be proved, but there is a good deal of evidence pointing that way. The influence of transplanted ovaries may be most beneficial in the prevention of degeneration of the ovaries, but as yet too few cases have been reported to be conclusive. All the evidences adduced tend to strengthen the view that the whole ovary, or if that be impossible, at least a portion, should be left in all operations where the condition of the patient will permit.

59.—See abstract in *THE JOURNAL*, xxxvii, p. 995.

**60. Tonsillar Keratosis.**—The conclusions of Wood's paper are as follows: "1. The disease commonly called mycosis pharyngitis leptothrixia is a true keratosis of the epithelium lining the crypts of the tonsils. 2. The leptothrix buccalis maximus, the bacillus buccalis maximus, and like organisms, do not possess any etiologic importance, but are present simply as saprophytes. 3. The disease is probably the result of a moderate degree of inflammation of the parenchyma of the tonsil, causing an increased growth of the normal epithelium of the crypts."

64.—See editorial in *THE JOURNAL* of February 22, p. 519.

**66. Dermoid Cysts.**—These cysts are described by Christian, who summarizes as follows: "1. Dermoid cysts and teratomata of the anterior mediastinum occur infrequently, generally give evidence of their presence during early adult life, and are of relatively long duration. 2. Their most frequent position is immediately behind the upper portion of the sternum. From there they may grow out into the lung or down between heart and lung. 3. These tumors may be classified as follows: (a) Tumors of ectodermal origin with the addition of some tissues from the mesoderm—dermoid cysts. (b) Tumors derived from all three germ layers—teratomata. (c) Dermoid cysts or teratomata which in some part of their structure show evident malignancy. The first class includes a large proportion of the reported cases. 4. The coughing up of hair is pathognomonic of this mediastinal condition. 5. Cure is possible only through surgical procedure. 6. The genesis of these tumors is to be referred to the fetal period of life. The origin of most is branchiogenic. Some may result from germ layers misplaced at the time of closure of the anterior chest wall."

**67. Intestinal Movements.**—Cannon has investigated the movements of the intestines with the Roentgen rays, using bismuth subnitrate mixed with food. He thinks the most notable activity of the small intestines is in the simultaneous division of the food lying in a loop into small segments and a rhythmic repetition of the division without any notable advance of food through the gut, mixing up the food and the digestive juices and bringing them in contact with the absorbing mechanism. Peristalsis is usually combined with segmentation. As the food is advancing, interfering constrictions often momentarily separate the rear end of the mass from the main body. The ileocecal valve is perfectly competent to prevent the repassage of food from the colon. The usual movements of the transverse and ascending colon and the cecum are antiperistaltic, occurring in periods about fifteen minutes apart. Thus the food in the closed sac is thoroughly mixed and again exposed to the absorbing wall without any interference with the processes in the small intestines. There is a gradual pushing, however, of the food forward. In emptying the large intestine, the material in the lower descending colon is first carried out by combined peristalsis and the pressure of the abdominal muscles. The remainder of the material is then spread into the evacuated region and this region again cleared. There is no evidence of antiperistalsis in the small intestine. Signs of emotion, such as fear, depression or rage, are accompanied by a total cessation of the movements of both the large and small intestines. The movements continue in the cat during sleep.

**68. Leucocytosis After Violent Exercise.**—The following are Larrabee's conclusions: Violent, prolonged, exhausting work produces a leucocytosis. This leucocytosis is made up principally by an increase in the polymorphonuclear cells, but the other forms may also be considerably increased in numbers. More than one cause acts to produce the leucocytosis, probably a temporary, mechanical cause, and also a toxic cause, more slow to develop, but lasting as long as the exercise continues."

**69. Tubular Perivascular Sarcoma.**—After reporting cases in detail and discussing the literature as to the origin, etc., of this class of tumors, Low and Lund say that in reviewing the history in connection with the pathological findings the chief conclusions to be drawn are as follows: "1. A pigmented growth of the skin may at any time take on malignant characteristics. 2. If the removal of a pigmented growth be undertaken at all, it becomes important for the surgeon to cut wide of the growth, as is the rule in carcinoma. All pigmented tissue should be removed practically in one piece, and without cutting through the tumor tissue. 3. Metastasis may take place from the peripheral organs to the brain, without the lungs being involved. 4. A melanotic sarcoma of the skin may in its metastases assume the type of a perivascular angiosarcoma."

75.—This article has appeared elsewhere. See *THE JOURNAL* of January 18, ¶9 and ¶10, p. 202.

**81. Electricity in Renal Disease.**—Rockwell finds that electricity is of value in certain cases of kidney disease. He

uses a high-tension faradic current in seances of not more than ten minutes' duration at first, but increasing to longer periods and employing as strong a current as the patient can reasonably bear. He also uses, in some cases, in connection and alternation with this, the static wave current, which has an advantage over the other of exceeding it in frequency and tension. He finds as a result of these infinitely rapid vibratory disturbances, which cause no pain or fever, a very marked influence on circulation and compensation. They affect the general nutrition at the same time. He also uses the older method of general faradization for its influence on the systemic nutrition.

**88. Hot-Air Treatment in Rheumatism.**—Gold finds the use of hot air exceedingly valuable in the treatment of chronic articular and muscular rheumatism and neuralgias, and thinks it not sufficiently appreciated by the profession. He uses the Betz's apparatus made in Chicago, but all others embody the same principle and probably may be equally effective. He reports several cases of rheumatic sciatica and gonorrheal rheumatism in which cure was effected by this remedy.

96.—See editorial in this issue.

**100. Pleurisy.**—Porter's paper reports a number of cases where difficulties in the diagnosis of pleurisy affected the treatment. They show the ease and accuracy with which most cases can be diagnosed, especially if the aspirating needle be used. They also show that at times it is almost impossible for even the best-trained diagnostician to be absolutely certain of the pathologic conditions, and that errors in diagnosis may result in permanent damage and possibly death, especially if the most scientific methods of treatment are not adopted early. They also illustrate positively the good results following free opening, meaning by this resection of the rib, cleansing of the pus cavity, and that small and valvular openings do not give the same favorable results.

**101. Heart Disease.**—Satterthwaite's paper aims to show that in the modern treatment of heart disease "milder methods are replacing older ones—in particular, that the idea of absolute rest has been superseded by rest alternating with physical activity; that venesection has been supplanted by restoration of the capillary circulation, mainly by resistance exercises and carbonated baths; hydragogue cathartics are in general to be replaced by stomachics, mild laxatives and diuretics; heart stimulants by general nerve tonics or sedatives and nutrients; while drugs of the digitalis group are being gradually avoided, except in particular instances, for the reasons that have already been given."

**114. Diagnosis.**—Webster describes the methods of teaching diagnosis in the Northwestern University Medical School, summing up as follows: "A combination of didactic lectures, recitations, laboratory work in normal diagnosis, clinical laboratory work, amphitheater clinics, ward visits and hospital clinics so arranged as to secure the greatest economy of the student's time with a maximum of individual instruction. Education in methods with the dominant idea that 'the whole art of medicine consists in observation.' Especial value placed on thorough training, in the laboratory work of normal physical diagnosis. Teaching one thing at a time and never taking the student out beyond his depth. Teaching all students how to write a concise, accurate clinical history and to make a general examination before taking up special examinations. Teaching them to reason rather than to memorize, a drawing out rather than a pouring in."

121.—Published in *THE JOURNAL*, xxxvii, p. 1671.

126.—See abstract in *THE JOURNAL*, xxxvii, p. 714.

**138. Tuberculosis in Canada.**—According to the résumé of the statistics here given by Lusk, it would seem that there has been no decrease in the last 25 years in the proportion of deaths from tuberculosis in Canada, while in England and the United States there has been a large decrease. Death returns from this scourge are there as great as those of the combined diseases of influenza, pneumonia, diphtheria and croup; as great as those from the diarrheas, heart disease and cancer; and greater than the mortality following pneumonia and the diarrheas of children and adults. Other noteworthy features are the frequency

of meningeal involvement in Montreal, causing 15 per cent. of deaths, and that almost 10 per cent. are in children under one year; that 15.1 per cent. die between 20 and 24, and 12.5 per cent. die between 25 and 29. The death-rate in males is greater in the first decade and during and after the seventh, while among females it is greater between 10 and 40 years, reaching its maximum between 10 and 20. The disparity between urban and rural population is also noticed, the town inhabitant being almost twice as liable to infection as the dweller in the country. Altitude and soil exercise a considerable influence in increasing the liability; the large percentage of infection following repeated colds, debility, and those associated with pleurisy are also noted.

**142. Treatment of Carcinomatous Growths by Caustics.**—Robinson holds that cutaneous epithelioma can be removed by caustics by completely necrosing only the small part of the area invaded by the disease, and that excision by the knife should be employed only when the case can not be treated by caustics, which is very rare in cutaneous cancer, or where the operation would cause no deformity as on the scrotum. For deep-seated rodent ulcers and possibly for cancer of the penis, the Roentgen rays should be tried. The chief claims which he makes for caustics are that the deformity following the operation is much less than after excision, and especially that reappearance of the disease is rare after their proper use.

144.—See abstract in *THE JOURNAL*, xxxvii, p. 853.

**151. Floating Kidney.**—Under this title of "floating kidney idolatry" Rose argues against the importance of this anomaly. He believes that great benefit may be often obtained by strapping of the abdomen in patients who have splanchnoptosis and that it does more good than nephropexy in these and in consumption. His experience tells him that one is not justified in resorting to operation, to perform nephropexy in cases of splanchnoptosis without first having tried the method of supporting the abdominal muscle and that the method of strapping seems to be the best of all. He also holds that we are not justified in pointing out the floating kidney as being especially the cause of gastric and nervous symptoms in cases of splanchnoptosis.

4. Gastric Ulcer.—Box holds to the infective theory of gastric ulcer; in any part of the intestine below the duodenum the infective nature of the ulceration has been accepted. Therefore, the same might reasonably be supposed to hold for gastric ulcer. It is not uncommon to find multiple ulceration both in the stomach and duodenum and so placed, either opposite or so close to each other, that infection from one to the other may have easily occurred. The appearance of a recent acute ulcer at the time of the operation for perforation is itself highly suggestive and this first led him to the infection theory. There is a zone of highly edematous and softened tissue surrounding it. This is not present in every perforated ulcer, for there is a form which he calls secondary which is due either to the rent of the thin peritoneal base or the tearing of an old adhesion, uniting such an ulcer to the surrounding tissue. This may be due to overdistension of the stomach or some unwonted muscular exertion, etc. We must, therefore, modify our views of gastric ulcer somewhat and admit the widespread inflammatory condition in some cases. He thinks the following points

should be borne in mind in the investigation of supposed gastric ulcer: "1. The patient's statements as to the occurrence of hematemesis should be received with due reserve, and corroborative particulars inquired for. 2. In doubtful cases it is necessary to see the vomited materials oneself if this be possible, and better still to observe or have observed the actual act of vomiting. 3. In all cases the urine examination should be a routine procedure. This examination should be thorough, and include the search for casts as well as for albumin. A single examination is often not enough. 4. The eyes should be always examined, particularly with a view to the presence of the normal light reflex, and the occurrence of changes in the fundus. Optic atrophy may put us on the track of locomotor ataxia; the presence of optic neuritis may reveal an unsuspected cerebral tumor, and the presence of neuro-retinitis may indicate renal disease. 5. An examination of the stomach contents for the presence of excess of free HCl should always, where practicable, be made. And if the first examination be negative a second should be undertaken before being positive as to its absence. Hyperacidity is a valuable, although not absolutely constant, sign of gastric ulceration. 6. Every patient in whom gastric ulcer is diagnosed should be looked upon as seriously ill. The disease is commonly treated much too lightly, considering its liability to such serious and fatal complications. I believe that prolonged rest in bed and proper dieting for some time is essential in all early cases."

**5. Malignant Intestinal Obstruction.**—Bidwell confines his remarks mainly to obstructions in the ascending and transverse colon, and remarks that in operation the use of the Murphy button should be avoided. In anastomosis between the ileum and colon he would open the abdomen in the middle line, introduce two fingers and explore the sigmoid to find whether it is dilated. If dilated follow it down with the finger until the obstruction is felt. If this is movable and capable of being brought outside the abdomen its removal should be attempted, but if it is too low down or fixed by adhesion, colotomy is required. In either case another incision should be made in the lower iliac region. In the case of a movable growth it should be brought out through the second incision and great assistance is obtained by using the fingers of the other hand inserted in the abdomen through the median incision. "When the growth and knuckle of the sigmoid have been prolapsed through the wound the gut should be divided above the stricture and a Paul's tube inserted and tied into the lower end of the descending colon. The sigmoid is then divided below the growth and a small Paul's tube inserted; a wedge-shaped piece of mesentery is now removed in which some enlarged gland may be found. The two portions of the intestine, viz., the lower part of the ascending (?) colon and the lower part of the sigmoid, are then united together with five or six silk sutures so as to bring a considerable amount of their serous surface into apposition, thus paving the way for the closure of the artificial anus." If the growth is immovable or too low down colostomy is performed, and in this case he employs the following method to prevent the passing of the feces toward the rectum: "After the peritoneum has been sutured to the skin in the ordinary way a portion of the sigmoid is prolapsed, and a hole is torn in the meso-sigmoid; the two edges of the skin nearly at the center of the incision are then brought together within the rent of the meso-sigmoid so that, when the operation is completed the upper and lower openings of the bowel are separated by a bridge of skin about half an inch wide. Two stout silk ligatures are then passed through the hole in the meso-sigmoid, and an incision having been made into the loop above its center, a Paul's glass is inserted and tied in with one of these ligatures. The lower end of the gut is also tightly ligatured with the one piece of silk. The loop of gut between this ligature and the part where the glass tube is tied in will slough away at the end of a few days, and the tube itself will fall off, leaving the two openings completely separated and flush with the incision. If the sigmoid should be found to be empty it is best immediately to examine the cecum. In the very few cases in which the obstruction is situated in the small intestine the cecum, of course, will also be collapsed, and the ileum leading to it will

be empty. In these cases it will be necessary to follow up the collapsed portion until the seat of the obstruction is reached. This is best done by bringing the contracted portion outside the abdomen, and returning it as soon as the growth has been reached and brought into view. When dealing with the small intestine, removal of the growth, followed by a primary end-to-end anastomosis, is the best treatment, the anastomosis being completed with sutures or possibly with a Murphy button." He has never removed the growth in the small intestine, but in several cases of acute obstruction, leading to gangrene, he has been obliged to do a primary resection, and in three of these the result was perfectly satisfactory. If the growth is situated in the cecum it will be felt at once. The small intestine will be gradually distended while its walls are considerably thickened. If the cecum is freely movable and is not bound down by adhesions it should be treated in the same way as the sigmoid, that is, brought out after another incision has been made, and the growth cut away after tubes have been tied in the ileum and ascending colon. The fecal fistula will be closed later by an anastomosis between the ileum and the ascending colon or this anastomosis may be made at once, leaving the removal of the growth until the patient is recovered from the effects of the obstruction. This method, however, he does not recommend. The above applies to movable tumors. If the growth is immovable only palliative treatment is indicated. He does not recommend an artificial anus at the cecum in these cases, but anastomosis by the above method of the ileum with the sigmoid is preferable. He reports several cases, and concludes that colostomy should never be performed for any growth which is situated above the middle of the sigmoid flexure, and that an artificial anus formed in such a case should be only a temporary one left after the removal of the growth and subsequently to be closed by ileo-sigmoidostomy.

**7. Optic Neuritis.**—The object of Hawthorne's article is to support the view that double optic neuritis, occurring in a patient the subject of chlorosis, is due to intracranial thrombosis. The case observed, in which the ocular paralysis was associated with double optic neuritis, raised with him the question whether the latter occurring alone with chlorosis was due to the same cause. In his case the ocular paralysis and ocular neuritis were undoubtedly, he thinks, due to a common cause. There is one condition, namely, intracranial thrombosis, capable to produce them, and from this he reasons that when unattended by ocular or other evidences of cerebral disturbances the occurrence of optic neuritis in chlorosis is also to be referred to cerebral thrombosis. That thrombosis is to be numbered among the possible complications from chlorosis is not in question. Professor Welch has collected 82 cases and believes more could be gathered by a thorough overhauling of the literature. Chlorosis, he says, "must be given a leading place among the causes of spontaneous thrombosis of the cerebral veins and sinuses in women." It is certain that double optic neuritis may be connected with the symptoms of such thrombosis, and Hawthorne quotes various authorities to prove this. The arguments may, therefore, be briefly presented as follows: "The simultaneous occurrence of the optic neuritis and sixth nerve paralysis suggests a common origin; the nature and temporary duration of the two events make it difficult to imagine any single cause capable of producing them other than an intracranial lesion; an intracranial thrombosis may certainly produce them; intracranial thrombosis is a recognized possibility in chlorosis; the patient is the subject of chlorosis; therefore it may be concluded with a considerable measure of confidence that both the optic neuritis and the sixth nerve paralysis were due to intracranial thrombosis. From such a conclusion, it is but a step to the proposition that thrombosis is probably the cause of optic neuritis when this occurs in chlorosis apart from other incidents having a possibly cerebral origin. The invitation to take that step is rendered more pressing when it is perceived that from cases of chlorosis with optic neuritis and severe cerebral disturbances a series of cases of gradually diminishing severity can be traced downward to the instances in which chlorosis is complicated by optic neuritis as the single event having thrombosis as the possible interpre-

tation. At one extreme are fatal cases in which delirium, coma, hemiplegia and double optic neuritis have been shown by necropsy to be associated with thrombosis of the intracranial veins and sinuses; following these are instances of less severe, though considerable, cerebral disturbance, with optic neuritis and evidences of thrombosis in the veins of the limbs or other parts of the body; these are succeeded by examples of chlorosis with headache more than usually extreme, more or less vomiting, and an ocular paralysis; next may be placed cases—like the one reported with this paper—in which the symptomatic disturbances other than those common in chlorosis are restricted to an ocular paralysis and double optic neuritis; and last of all are those in which the optic neuritis is the sole unusual event. Such a gradation is certainly an impressive one, and may reasonably be presented in support of the proposition that in these different groups we have to deal with different degrees of severity and extent of one and the same pathological process, and that the pathological event underlying them all is a thrombosis of the intracranial sinuses and veins." Another series of evidences which he thinks supports these views is the occurrence of optic neuritis in ear disease, and the optic neuritis developing after a considerable hemorrhage. As to the mechanism it is not necessary to assume that to produce optic neuritis a thrombosis must be so situated as to interfere with the venous return of the eyeball. A thrombus once formed is for all practical purposes a tumor in that it is a foreign body within the skull. Whatever conflict of opinion may yet exist about the manner in which cerebral tumors cause optic neuritis it is certain that neither the size nor the position of the tumor is the determining factor. A thrombus, therefore, he thinks, behaves as other forms of tumors and produces the symptoms which we would observe in connection with cerebral tumor. The principal deductions he draws are that there is probably cardiac weakness, a sluggish state of the circulation and that the immediate risks are that the thrombus will grow over a larger area and that a portion will become detached and lead to embolism. To prevent the latter result complete rest is imperative, but we should take steps at the same time to keep up the vigor of the circulation so as not to favor the extension of the thrombus and, therefore, it would be wise to supplement the administration of iron with cardiac tonics as digitalis and diffuse stimulants, more particularly ammonia. After the above measures have assured with reasonable certainty that the danger of extension of the thrombus is probably over we should try to increase the vigor of the vital processes by moderate exercise.

**14. Word-Blindness.**—Hinshelwood reports several interesting cases of word-blindness, in one of which, in an educated man, there was a complete aphasia, both motor and sensory, but a gradual improvement occurred so that in about a week he could express his ideas. There was a trace of auditory aphasia still left, but word-blindness was the most prominent symptom. There was no letter blindness. Of the four languages which he read, Greek, Latin, French and English, his knowledge of Greek was complete; in Latin he was a little less perfect; in French he was better than in English, and in his mother tongue he was the least perfect. There was evidence or suspicion of a specific disease, and he was put upon specific treatment, with the result of a very pronounced improvement in all respects, though there still remains apparently some traces of the difficulty in reading English. It requires greater mental concentration, he says, to read English than to read Greek or Latin. While this is the first case Hinshelwood met with the different degrees of word-blindness in different languages, he has met with a case where the patient was word-deaf to one language and not to another. In two of the cases reported the word-blindness was associated with right lateral homonymous hemianopsia, in one case temporary, in the other permanent. In three of the four cases there was recovery; in one the word-blindness persisted. The recovery will depend on whether the centers or the fibers leading to it have been destroyed, in which case the loss will be permanent, or whether its function has only been suspended by its blood supply being interfered with, either by pressure of a growth or by hemor-

rhage, or by an occlusion of a cerebral vessel by a thrombus or embolism. With no actual destruction of cerebral tissue recovery may take place, but one can never say whether the loss will be permanent. If there is any suspicion of a syphilitic taint, specific treatment should be employed. In cases of permanent destruction of the visual memories or words or letters re-education is the only resort. This should not be begun as long as there are any traces of active cerebral disease present. The chances of success will be greater with young patients. He holds, and thinks these patients prove the truth of his published statement "that all the varieties of word-blindness met with in clinical experience can be intelligently explained by regarding them as disorders of the visual memory produced by lesions affecting more or less completely a definite area of the cerebral cortex in which are preserved these past visual impressions arranged in definite and ordered groups."

**16. Acute Suffocating Pulmonary Edema.**—Lissaman reports a case of this kind in which he tried nitrite of amyl with unsatisfactory results. He then tentatively employed chloroform with the best of success. He holds that in this condition, which might be called a sort of wet asthma, the lungs are, perhaps, in a similar condition to the extremities in certain forms of erythromelalgia, and relies on chloroform as the remedy in the future.

**17. Auscultation.**—Syers claims that the use of the binaural stethoscope is damaging to correct auscultation and that the instrument is unreliable as regards the investigation of the heart sounds, and that if its popularity is continues, at least aortic regurgitation will be a disease which can not be certainly diagnosed. He maintains that many cases of this sort are overlooked through the unsuitability of the instrument in the hands of the examiner. The soft low pitched murmur due to incompetent aortic valves is inaudible or unnoticeable by this instrument. He also holds that in lung examination beginners who use this instrument never really appreciate the difference between bronchial, tubular and cavernous breathing. Another objection to it is the compression of the delicate organs of hearing by the ivory heads and the unyielding spring of the binaural stethoscope. This pressure kept up intermittently for long periods for hours, as is the case with house surgeons and others, may be most injurious to the hearing of the observer. He does not deny that the instrument has a certain value. It is convenient in illnesses which render it difficult to move the patient in a manner suitable for examination by the wooden stethoscope, but here it is only an accessory, needed for particular occasions and special needs. What he protests against and in the strongest possible manner, is the predilection shown for the binaural stethoscope by the young student who is allowed to make use of it at the very commencement of his clinical work so that he is totally unable to appreciate the advantages of the old-fashioned instrument. This he has found the cause of much of the indifferent diagnosis of chest diseases so often observed at the present time.

**18. Fourth Disease.**—Ker discusses the symptoms in measles, German measles, and scarlet fever, with special reference to the occurrence of the "fourth disease" described by Dr. Dukes. The conclusion which he reaches is that, while he had accepted its occurrence previously and endeavored to find facts to support the claim, after eighteen months and in face of the criticisms on the subject he feels only one verdict is possible regarding the contention of Dr. Dukes. It is, namely, the Scottish one, of "not proven."

**20. Auscultatory Percussion.**—Habersohn's article is a plea for the greater use of auscultatory percussion, which he thinks is neglected by the profession; while it has its limitations and its value may be exaggerated, he thinks it is a physical sign which should never be ignored.

**21. Floating Kidney.**—Hutchinson does not find sufficient evidence of the hepato-renal bands of peritoneum described by Weisker to account for the obstructive jaundice produced in certain cases. He thinks that jaundice may be caused, either by downward displacement of the duodenum with stretching of

the common bile-duct, by displacement of the gall-bladder and sharp kinking of the cystic duct, or by torsion of the vertical part of the duodenum and perhaps even of the bile-duct, and that in one of these conditions an explanation is usually to be found, and not in traction through bands of the peritoneal investment of the right kidney connecting it with the liver. The latter may possibly be the fact in certain cases, but he has not found convincing evidence of it where he has been able to investigate.

**22. Uremic Ulcerations of Stomach and Small Intestine.**—Mathieu states that the prognosis of uremic ulcerations in the intestines is always grave, but healed lesions have been found at autopsies, showing that recovery may occur. He has been able to find 22 cases in the literature; 12 of the 20, in which the age was mentioned, were between 18 and 24 and one was 14. Pain is rare and diarrhea the rule, but in a personal case, pain was intense and the patient constipated. She was a young woman presenting the clinical picture of chronic Bright's disease, hypertrophy of the heart and bruit de galop. Five small ulcerations were found in the stomach, corresponding to similar lesions in the intestines, and also a large ulcer with all the characteristics of simple gastric ulcer. All the lesions in the stomach were evidently recent. They had been unaccompanied by any of the usual symptoms of gastric ulcer. He believes that this is the first case of the kind on record.

**26. The Hospitals of St. Petersburg.**—Marcou speaks with envy of the management of the St. Petersburg hospitals, which are entirely under the charge of medical men. The attendants are trained nurses and the wards are kept clean by expert cleaners. All appointments are entirely free from politics. There are 169 hospitals and medical institutions and nearly \$17,000,000 is spent annually on the care of the sick and poor.

27. See editorial in this issue.

**28. Treatment of Club-Foot by Ablation of All the Tarsal Bones Without Immobilization or Apparatus.**—Lucas-Championnière has treated 31 cases of club-foot by a method which has proved uniformly successful in his experience extending over a period of thirteen years. He thinks that it is much more important to conserve the muscles and tendons than the tarsal bones, which are all more or less altered in shape and size and displaced in a club-foot. Through a single incision in the dorsum of the foot, he removes the astragalus, scaphoid, cuboid and the three cuneiform bones and sometimes the rear end of the fifth metatarsal bone. The posterior third of the calcaneum is all that is left, and sometimes only the insertion of the tendo Achillis. This resection of both groups of the tarsal bones enables the foot to be modeled into a good shape. The metatarsus fits against the remainder of the calcaneum, thus shortening the foot somewhat. The worst deformities can thus be completely corrected and the foot restored to normal appearance and function. No orthopedic apparatus of any kind is applied. The subject wears an ordinary shoe, or one made a little more solid than usual. Mobilization is commenced the fourth day, and the patient commences to use his foot the third to the sixth week. Of all the methods of correcting club-foot in vogue, this is the simplest and the surest, under thorough antisepsis. The patient presented at the Académie was a man 31 years of age. One foot had been operated on with complete success the year before, and the other was soon to be treated in the same way.

**29. Modifications of the Reflexes of Traumatism of the Spine.**—Lambret describes the case of a young man whose spinal cord had been severed by a bullet near the fifth dorsal. There was complete anesthesia and motor paralysis below the nipple line, and the reflexes in the legs were abolished except for a very slight flexion of the toes when the sole was stimulated. The slight persistence of this reflex shows that Bastian's law is too absolute. In another case, mere compression of the spinal cord by a small exudation completely abolished the reflexes of the legs. These and other facts which he cites sustain his assertions that the brain participates to a considerable extent in the production of normal reflexes.

**30. Chronic Splenomegalia.**—Delcœur classifies chronic splenomegalia as primary and secondary. Tuberculosis may induce either form and, besides the classic symptoms common to all cases of chronic splenomegalia, there may be an excess of blood corpuscles and cyanosis. Three cases of this kind are on record. In one there were eight to nine millions of reds, but they were not deformed nor nucleated. Vaillard suggests that this hyperglobulia may be due to the loss of the spleen function which normally destroys the excess of corpuscles. The spleen is very large in syphilis neonatorum, but subsides to normal size by the third to the fourth month. It is also hypertrophied in the first period of acquired syphilis and this condition may persist into the second stage. The diagnosis of the different forms of the lymphogenic diathesis depends principally on the blood count and the exclusion of tuberculosis, syphilis and acute infections affecting the adjacent organs. Treatment has been occasionally successful with the iodides, mercury, phosphorus, arsenic or tonics in certain cases, and it is advisable to try one after the other. Hayem gives the preference to arsenic. Organ treatment of leukemia with spleen and lymphatic extract has not been successful to date. Surgical intervention is absolutely contra-indicated in the various forms of leukemia, but may be required in chronic malaria. In leukemia, syphilis, tuberculosis and liver affections, splenectomy does not induce any improvement but rather seems to hasten the fatal termination.

**35. Traumatic Scarlet Fever.**—De Bovis has collected 147 cases of traumatic scarlet fever; 80 per cent. of the patients were under 15 years of age and two-thirds of the total number were males. Many of these cases were evidently merely ordinary scarlet fever occurring in a person who had been wounded in some way, but a large proportion remains in which the scarlet fever was evidently the direct result of the traumatism. This form differs from the first by its shorter incubation, the insignificance of the sore throat, the smaller proportion of young children and the earlier appearance of desquamation, but more than all by the development and spread of the eruption. It usually starts in the peripheral wound and thence spreads like a lymphangitis, finally invading the entire cutaneous surface. This course is extremely abnormal if we assume that the infection occurs by the usual routes, but it is easily explained by the penetration of the scarlet fever germs through the portal of entry afforded by the wound. The scarlet fever in this case is inoculated. It may transmit the disease and start an epidemic. A traumatism evidently engenders a peculiar receptivity to scarlet fever infection, which surgeons should bear in mind in operating after contact with scarlet fever patients.

**40. Organotherapy of Pancreatogenic Fatty Diarrhea.**—Salomon, assistant at von Noorden's clinic, reports the successful administration of a preparation of pancreas substance in two cases of fatty stools associated with diabetes. There are scarcely twenty-four such cases on record. The pancreas must be totally impotent, with entire loss of its secretory function, or else the pancreatic juice must be completely shut off from the intestines. In either case, organotherapy promises benefit, and administration of pancreas substance has been successful in the experience of von Noorden, Pribram and others. Pankreatin (Rhenania) and pankreon were even more effective than the gland substance, while far more convenient.

**42. Connection Between Psoriasis and Glycosuria.**—Pick examined 50 patients with psoriasis and 50 with other cutaneous affections for alimentary glycosuria after ingestion of 100 gm. of grape sugar. He found it in only 2 of the first group and in 3 of the second.

**44. Rapid Test of Quantity of Uric Acid in Urine.**—Ruhemann's test is based on the principle that iodine is neutralized by a certain proportion of uric acid until the brown color vanishes completely. He has calculated the exact amount of each necessary to determine the percentage of uric acid in a given amount of urine, and established a graduated scale. He calls the test tube and stopper graduated for this scale, the "uricometer," and states that this quantitative test is simple,

reliable and can be made by any physician. The test is complete in thirty to forty minutes when the yellowish fluid formed by the mixture of iodine and urine has turned a milky white. Study of this reaction suggests that possibly drugs which readily and rapidly decompose iodine in the organism might be beneficial in gout and the uric acid diathesis, to increase the solubility of uric acid and the urates. Lithium iodide takes the lead in this respect. Iodine appears promptly in the urine when it is administered. He gives it in pills with bolus alba, commencing with 15 to 20 cg. three times a day after meals. It can also be administered in a subcutaneous injection in the vicinity of the point affected. The elimination of uric acid increases under its influence and it can be long continued, even at the same time as colchicine during the attacks. "For this and other reasons it is superior to urotropin and all other drugs recommended for gout."

**45. Mechanical Protection Against Infection.**—The formula of the varnish recommended as a covering for the hands by Kausch, is 200 parts resin; 200 parts absolute alcohol; 400 parts ether (sp. gr. .725), and 20 parts castor oil. He illustrates an apparatus for spreading it evenly on the hands.

**46. Improvements in Treatment of Lupus by Finsen's Method.**—Kattenbracker discusses the bactericidal action of the Kjeldsen portable iron therapeutic lamp, constructed on the same principle as those mentioned in THE JOURNAL of Feb. 8, 1902. He found that an exposure of one to sixty seconds enfeebled bacteria so that their further growth was much checked. In some of his tests the typhoid bacillus made no growth after a sixty seconds' exposure and the anthrax bacillus after thirty seconds. The cultures were all superficial. He concludes that these iron lamps constitute an improvement in light treatment of all kinds of skin diseases as they accomplish in three minutes with 5 amperes what is only possible with the Finsen apparatus with 70 or 80 amperes in an hour and with the constant aid of an attendant.

**48. Topography of Uterus and Bladder After Alexander-Adams Operation.**—Bullius found that the round ligaments retained or regained their complete functional capacity after this operation in three cases investigated. Their perfect function was best observed as the distended bladder was evacuated with a catheter.

**49. Nature of Dysmenorrhea.**—Theilhaber adds the following arguments to his previous statements in regard to the tetanic contraction of the circular muscles which he believes is the nature of the dysmenorrhea in certain cases: 1, the pain disappears after birth of first child; 2, the pain appears twelve to twenty-four hours before the menstrual flow commences, and the acme of the pains has passed before coagula form; 3, the pain is continuous, not intermittent like labor pains or those that occur in case of submucous myomata or perimetritis; 4, resection of the sphincter of the internal os cures the dysmenorrhea.

**51. The Nature of Fever.**—Aronsohn has continued his studies of the essence of fever and describes a number of interesting experiments on animals which seem to establish that fever is due to a morbidly exaggerated stimulation or irritation of the heat centers. The irritated centers incite the motor trophic apparatus of the muscles, including the muscles of the vessels, to increased production of heat and also to increased metabolism and alterations in the elimination of heat. The various types of fever are determined by the varying kinds of irritation brought to bear on the heat centers in the course of infectious diseases. This irritation is evidently multiple in its nature, and other centers in the brain and other organs are liable to be influenced at the same time. The fundamental type of fever, however, is the elevation of temperature induced by direct mechanical, electric or chemical stimulation of the heat centers in the absence of any morbid process in the organism. After inducing fever by puncture of the heat center in an animal, he excluded the muscles by paralyzing the intramuscular terminals of the motor nerves with curare. The temperature dropped at once by 0.23 Centigrade. The decrease

in the temperature is much more marked after curarizing in febrile than in normal animals. In tests on starving dogs he found that the temperature did not rise so high after puncture of the heat center as in normal dogs, and it remained below the fever limit. He found that it was possible to induce these high temperatures in animals on puncture of the heat center even after almost all the blood had been substituted by physiologic saline solution. This established that the blood could not be the seat of the heat production. The fact that the glandular system rests during sleep testifies that it can not be responsible for the heat production during fever. Ito has demonstrated that the liver has nothing to do with it. He holds the pancreas responsible, but his arguments are not conclusive, while Aronsohn has shown that the muscles generate fever heat even after the temperature in the rectum has fallen to normal, and commence to generate it before the rectal temperature rises.

**52. The Alkalinity of the Blood in Disease.**—Brandenburg calls attention to the fact that alkali occurs in the blood under two forms, that combined with carbon dioxide and that combined with albumin. The albumin compounds are very tenacious of their alkali and the two forms can be distinguished by their capacity for diffusion. If a parchment tube is prepared with a solution of sodium for dialysis and suspended in a glass of water, the alkali in the tube gradually diffuses through it until the concentration of the alkali on the inner and outer walls of the tube is the same. If blood be used instead of the solution of sodium, the amount of concentration on the inner and outer walls never becomes equalized, no matter how long the tube hangs in the water. The alkali bound in the combination with albumin does not diffuse. It is possible to use an alkaline solution instead of water for this test, the concentration so graduated that the blood neither loses nor gains alkali. The amount of concentration in the external fluid can then be accepted as the index of the amount of "alkali tension" of the blood. This "alkali tension" is thus a new means of estimating the properties of the blood, and will supplement the determination of the amount of albumin in it and the freezing-point. There seems to be a certain proportion between the alkali tension and the freezing-point. The alkali tension does not vary much from a certain standard, notwithstanding the fact that the total alkalinity of the blood may range within such wide limits without symptoms. In the serum, the alkali is about evenly divided between the bound and the diffusible form. In anemia about 33 per cent. of the total alkali is diffusible. The proportion is therefore dependent on the amount of albumin in the blood. The higher the total alkalinity, the lower the percentage of diffusible alkali, and *vice versa*, but the alkali tension remains approximately the same throughout. Possibly in the disturbances in metabolism, the acid intoxications, the chief symptoms may be due to the variations which they induce in the alkali tension. Brandenburg believes that the freezing-point is directly dependent on the amount of diffusible alkali in the blood, aside from cases of retention in consequence of contracted kidney, etc. The wide variations in the alkalinity of the blood with the comparatively insignificant clinical manifestations, suggest that it is not particularly important from a biologic view-point. But the constant value of the alkali tension suggests that it may be of moment to the vital processes, and should hence be taken into consideration in diagnosing disease. Recent research has shown that the bactericidal properties of blood are enhanced by increasing the amount of diffusible alkali in it. Hamburger found that after determining the bactericidal power of a blood, the addition of carbon dioxide releases the alkali from the albumin, increasing the proportion of diffusible alkali, and thus raises the alkali tension and has a marked effect in augmenting the bactericidal properties of the blood. The addition of an alkaline solution to the blood scarcely affects the alkali tension, as part of the alkali unites with the albuminoids, and the proportion between the bound and the diffusible alkali remains about the same. In normal blood about 20 per cent. of the total alkali is diffusible.

**53. Exophthalmic Goiter.**—Kocher's communication fills the entire 304 pages of this issue of the *Grenzgebiete*, and con-

cludes with a bibliography of 1423 titles. He describes his experiences with 93 cases of this disease since 1887, all treated on the same principle, that is, to put an end to the excessive vascularization of the thyroid gland with the smallest possible resection of tissue. He operated on 59, which is more than a seventh of all the operated cases of the disease previously on record. Of this number of 59, 45 are permanently cured, with in many cases not a trace of the former troubles to be detected; 8 are much improved, 2 slightly improved and 4 have died. When the operation succeeded in permanently modifying the excessive vascularization of the gland, the cure was rapid and complete. This occurred in 75 per cent. of all the cases. Only the hypervascular portion of the struma is important in this respect. The aim is to limit the supply of blood to the gland. Ligation of both superior arteries is an insignificant measure, but ligation of the afferent arteries and partial excision is effective in even the severest cases. Unilateral excision causes less hemorrhage than the bilateral. Koehler always proceeds gradually, watching the progress of the case, ready to operate more extensively if conditions require it, but he found that the desired results were accomplished in most cases by partial operations. The remainder of the gland spontaneously subsided in many instances, rendering further intervention unnecessary. In view of the favorable results he has attained, he counsels operation at once in every case, without wasting time on internal treatment. The operator should always avoid general anesthesia, and remember that the main point is scrupulously minute hemostasis. He asserts that it is well demonstrated that treatment with iodine has actually aggravated many incipient cases. Thyroid treatment is harmless. Hydrotherapy is always beneficial, and he always orders it in preparing his patients for an operation. Of his 93 cases, 37 were extremely severe; 22 well developed cases; 14 were cases of struma vasculosa (9 were operated on); 2 of a "pseudo-Basedow" (both operated), and 4 of transient. The exophthalmus vanished completely in only 26 of his 45 completely cured cases. In the others it persisted in a slight degree, probably owing to the anatomic alterations induced by the morbid process previous to the operation.

**54. Dangers of Taxis.**—Lanz has witnessed several cases in which an incarcerated hernia was reduced without much difficulty, but the results were disastrous. Some terminated fatally and others required an operation at once. Even when reduction was easy, a predisposition had been acquired, and the recurrence of the incarceration was in most cases only a question of time, with an operation required sooner or later. He has become convinced that taxis is below the level of modern science, and should be definitely discarded. An early herniotomy meets with much more favorable conditions for success than when the parts have been irritated by attempts at reduction. The narcosis induced for the taxis should be utilized for the herniotomy instead, or the latter be performed under local anesthesia with Schleich's solution. Lanz has had occasion to successfully perform a herniotomy on three children a few weeks old. He describes a number of instances of chronic ileus, perforation and peritonitis, which followed an unfortunately too successful taxis, and states that herniotomy should be proposed at once when the physician is summoned to an incarcerated hernia.

**55. Injuries from Powerful Electric Currents.**—Jessen reviews the list of such injuries on record and describes a personal case. All the symptoms suggest the possibility that the powerful current causes certain minute alterations in the brain like those observed in dogs under similar conditions. These induce the transient symptoms which indicate an organic lesion, although the symptoms in general are of a purely functional nature with hysterical features. All writers are unanimous in lauding the benefits of artificial respiration. D'Arsonval was able to resuscitate in this way a man who had been unconscious for hours after a current of 4500 volts had passed from hand to seat. Eulenburg observed a case of severe progressive epilepsy, followed by paralysis and blindness, in a man of 48 who had received a current of 500 volts.

**56. Treatment of Hemoptysis with Subcutaneous Injection of Gelatin.**—Thieme was much pleased with the results of the injection of 100 c.c. of a 2 per cent. solution of gelatin in 12 severe cases of hemorrhage from the lungs. The injection was made in the thigh, the part lightly massaged afterward. The temperature rose in all the patients except one, the maximum between 37.6 and 38.9 C. One patient had a temperature of 40.3 to 40.7 C. for five days. Another had been febrile for a long time, but the temperature dropped to normal when the hemorrhage occurred and the patient was dismissed later clinically cured. Only one of the patients succumbed to the hemorrhage. He renders the solution slightly alkaline with soda.

**57. Treatment of Dry Catarrh of the Middle Ear in the Pneumatic Cabinet.**—Hamm has utilized the pneumatic cabinet as a means of treating deafness from sclerosis of the middle ear. Transient improvement was noted in all the cases and 3 were very much improved. One was a young man who before treatment could not hear the ticking of a watch nor a whisper, and the speaking voice only at 26 cm. by the right and 17 cm. by the left ear. After treatment, he could hear a whisper at 148 cm. with one, and at 12 cm. with the other ear, and the speaking voice at 600 cm. with the right, and 65 with the left ear. This great improvement was not maintained, but the hearing remained permanently very much improved. Another patient before treatment could hear the speaking voice only at 260 and 130 cm. After six weeks of daily sittings in the pneumatic cabinet, he could hear the speaking voice at 100 meters and a whisper at 200 cm. He had been under various kinds of treatment before with no benefit. Hamm himself had suffered for eight years from chronic otitis of the middle ear, rebellious to all treatment. He could hear a whisper only at 14 cm. and 5 cm. before, but after treatment, at 130 cm. and 32 cm. This improvement yielded somewhat in consequence of repeated colds, but a new series of sittings restored it to the same point, where it has permanently remained. He could now hear so well inside the cabinet, while one patient could hear much better than at other times. Each seance lasted one or one-half hours. The pressure was gradually increased during twenty-five minutes and then reduced during the last forty. It was graduated to .5, 1 and 1.5 atmospheres. The treatment included 25 to 40 sittings. The improvement seemed to be progressive after treatment. He proposes to maintain the benefit by another course of a few sittings each year.

**63. Chronic Acid Diabetes.**—Kossa has established that most of the compounds of chromic acid, and especially potassium chromate, induce glycosuria in warm-blooded animals, most pronounced in dogs. This chromic acid diabetes belongs to the group of "kidney diabetes" like phloridzin diabetes. The proportion of sugar in the blood does not increase after the excretion of urine has been prevented.

**59. Lowering the Pelvis in Operations on the Biliary Passages.**—Ruehl proclaims that by lowering the pelvis so that the patient is in a half standing position in operations on the biliary passages, hemostasis is materially facilitated as the blood flows down without masking the field of operation. Over-sight of the field is much more complete.

**65. Carcinoma and Malaria.**—Prochnik is the retired chief of the medical department of the Dutch army in the East Indies. He states that carcinoma was not at all rare in his experience in Java, etc., and that as every one had malaria more or less, it must have accompanied or followed malaria infection in nearly every case. There is no antagonism therefore between carcinoma and malaria. On the contrary, he is inclined to admit that malaria is a predisposing factor in the evolution of carcinoma of the liver, the most common variety in his tropical experience.

**67. A New Reaction of Human Milk.**—Bordet has called attention to the precipitation of the albuminoids in milk when it is added to the serum of animals which have been previously injected with milk from the same source. Schlossmann found further that the fluid from a hydrocele on a breast child was

also able to precipitate the albuminoids in human but not in cow's milk. Moro now announces that if a few drops of human milk are added to a few c.c. of fluid from a hydrocele, in a few minutes the hydrocele fluid coagulates into a solid mass. This reaction does not occur with cow's or goat's milk. The hydrocele fluid evidently contains fibrinogen, and the milk, fibrin ferment. The combination of the two induces the coagulation. It occurs even with minute quantities of the milk; all the serum in contact with the milk coagulates around it. The same reaction occurs when human serum is added instead of the milk, but much less pronounced and much slower, and the same difference is observed when the human milk is boiled or long heated. Particles of coagulated ox blood also induced a slow and partial coagulation.

**70. Ship Physicians in the Byzantine Epoch.**—Bloch has found a reference in the works of Paulos of Aegina dating from the seventh century in which he speaks of the three classes of medical men: city, country and ship physicians.

**72. Origin of Syphilis.**—Scheube cites extensively from Spanish medical works of the time of Columbus which describe a disease found among the natives of Haiti by the Spanish explorers. It was mild among the natives, but proved virulent for the Spaniards who contracted it and infected others on their return. The description tallies exactly with that of syphilis, he thinks. He has become convinced that Haiti, and possibly the other West Indian islands, were the original source of infection with syphilis. It had probably not spread to the North American continent, as the natives on the continent were free from it and suffered from its ravages when it was introduced among them. The mildness of the disease in Haiti suggests that it must have been long established there. Pre-Columbian syphilitic relics could alone decide the question, but Virchow announced in 1895 that not a single pre-Columbian bone had yet been discovered which can be adduced as conclusive evidence in favor of the existence of syphilis.

**73. Value of the Gelatinized Urine Method of Bacteriologic Diagnosis of Typhoid.**—Strada found that Piorowsky's method is simple and reliable, but that it varies with the age of the cultures used. They should consequently be young and the plates should be kept at a constant temperature of 22 C. The urine should be from patients on a predominantly vegetable diet, as otherwise it is not sufficiently alkaline. The bacteriologic test proved positive in 20 out of 22 patients examined and enabled the diagnosis to be definitely established within twenty-four hours. The contradictory results obtained in other clinics are probably due to the progressive loss of their differential characteristics by the bacilli as they age. Piorowsky recommends to leave the normal urine for twenty-four to forty-eight hours, until it has become spontaneously alkaline, then add .5 per cent. of peptone, 33 per cent. of gelatin and boil for an hour at 100 C., then filter without heat, and distribute in test tubes, sterilizing it for fifteen minutes and again the next day for ten minutes. It is then poured on plates and sown with the suspected material. The colonies of the typhoid bacilli send out long tendrils while the outlines of the colonies of the colon bacillus are sharply defined with none of the straggling growth of the typhoid colonies.

**74. Treatment of Arteriosclerosis with Truncceek's Inorganic Serum.**—Zanoni confirms all that Truncceek claims for his serum. His experience includes three cases of severe arteriosclerosis treated with it. He ascribes the benefit derived to the chemical modification of the blood serum and the consequent stimulation of nutrition and function of the fibers in the heart and vessels.

**75. Treatment of Trigeminal Neuralgia by Resection of the Cervical Sympathetic.**—Cavazzani reports his third case of rebellious trigeminal neuralgia cured by resection of the cervical sympathetic. The benefit was not immediately apparent in any case, but became more and more pronounced with the lapse of time.

**76. Action of Anti-Periodic Drugs on the Parasite of Malaria.**—Lo Monaco and Panichi announce that a drop of a

solution of quinin added to a fresh specimen of malarial blood, affects the parasites in proportion to its concentration. A weak solution causes them to contract for a few minutes and then expand with marked pseudopodia. This condition of excitement is still more pronounced if a drop of a medium solution of quinin is added to the specimen, and it terminates in the escape of the parasite from the blood corpuscle. A still stronger solution permanently shrivels the parasite and it does not leave the corpuscle. They, therefore, administer quinin in malaria in the dose and solution equivalent to that which produces the detachment of the parasite from the corpuscle *in vitro*—the second phase of the action of quinin. They state that the smallest forms of the parasite are the most resistant to quinin, and that all the parasites grow more resistant the longer the interval since the febrile attack. They conclude from the latter fact that there must be some substance in the blood at the time of the attack which has an antiparasitic action and the effect of quinin administered at this time is re-enforced by this substance already in the blood. This antiparasitic substance affects all the forms of malaria and all species of the malarial parasite with the sole exception of the young unpigmented variety found in estival tertian. The pigmented forms, on the other hand, are resistant to the action of quinin during apyrexia; but become less resistant during a febrile attack and can then be detached from the red corpuscles with a comparatively weak solution of quinin. But when the malaria has assumed the pernicious form, both the pigmented and the non-pigmented forms display great resistance, probably owing to the absence of the antiparasitic substance in the blood under these conditions, or the presence of some yet unknown antagonistic substance. The quinin behaves the same whether in a solution of distilled water or in a .38 per cent. saline solution. A stronger saline solution prevents these phenomena.

**77. New Method of Isolating the Typhoid Bacillus.**—Cambier proposed recently to utilize the property possessed by the typhoid bacillus of passing through a Berkefeld filter, as a means of differentiating it. Biffi pointed out at the time that the test was unreliable as the bacterium coli also possessed this property. The latter now suggests a method of differentiating the typhoid bacillus by the combination of these two phenomena, and in this preliminary communication lauds this latest method as simple, convenient and reliable. The material to be examined is sown in bouillon containing a certain amount of serum known to agglutinate the bacterium coli. The latter as it develops becomes agglutinated, and hence is unable to pass through the filter with which the test tube is supplied, while the typhoid bacillus passes through it and develops in pure cultures on the farther side. The test can be reversed and pure cultures of the colon bacillus be derived by substituting a serum that agglutinates the typhoid bacillus. The colon bacillus agglutinating serum must be prepared by inoculation with different species of colon bacilli, so that the agglutinating effect will be certain. The effect must also be tested to determine the proper dilution, as an excess might affect also the typhoid bacillus, while if too weak it might fail to agglutinate all the colon bacilli.

## Queries and Minor Notes.

### DISCOVERY OF CHLOROFORM AND ETHER.

LEBANON, ILL., Feb. 17, 1902

To the Editor:—Will you please state in THE JOURNAL the facts regarding the discovery of chloroform and ether as anesthetics? Were these chemicals in use before their use as anesthetics? Who first used each and both as anesthetics?

J. H. F.

ANS.—Chloroform is said to have been discovered in 1831, independently by Liebig, Soubeiran, and Guthrie; its chemical composition was first determined by Dumas in 1834. Chloroform was experimentally studied by Flourens in 1847, and was first employed in surgical anesthesia on Nov. 15, 1847, by Sir James Y. Simpson, in Edinburgh. It had previously been used in obstetrics. Ether was discovered, it is said, by Valerius Cordus, in 1540, and was called by him *oleum vitrioli dulce*. Another authority says that the substance was discovered by an Arabian chemist, Djabar Yeber, and its method of manufacture by Dr. Michael Morris. It

was employed as early as 1785, as an inhalation for asthma, and its narcotic properties caused it to be used in the treatment of phthisis early in the nineteenth century. About 1840 it was common among medical students to inhale ether in order to experience the exhilarating effect. In 1842, Dr. Crawford W. Long, of Jefferson, Jackson County, Ga., administered ether for the removal of a small tumor and for several subsequent minor operations. William T. G. Morton, a dentist of Boston, also claimed to have been the first to employ ether as an anesthetic, and he administered ether on Oct. 17, 1846, in the Massachusetts General Hospital for Dr. Warren. The question of the priority of the use of ether is a vexed one and has provoked much acrimonious discussion.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 30 to Feb. 12, 1902, inclusive:

Robert A. Anderson, contract surgeon, from Clarksdale, Miss., to duty at Fort Duchesne, Utah.

Peter W. Beckman, contract surgeon, from Fort Duchesne, Utah, to Alton, Ill., for annulment of contract.

Justus M. Brown, colonel and asst. surgeon-general, to report in person to the Surgeon-General in Washington, D. C., on official business of the Medical Department and thereafter to return to his proper station in New York City. George H. Cassaday, contract dental surgeon, now at San Francisco, to proceed to Manila, P. I., for assignment to duty.

James B. Ferguson, contract surgeon, former orders so amended as to direct him to proceed to Fort Sheridan, Ill., for duty at that post.

James D. Glennan, major and surgeon, U. S. A., on his arrival in San Francisco, to report to the commanding general, Department of California, to relieve Major Robert J. Gibson, surgeon, U. S. A.

Harry Greenberg, contract surgeon, from Milwaukee, Wis., to San Francisco, en route for assignment in the Division of the Philippines.

Hubert Grieger, contract surgeon, from South Milwaukee to San Francisco, en route to the Division of the Philippines.

George L. Hicks, contract surgeon, now at Cambridge, Md., will proceed to Fort Totten, N. Y., for temporary duty.

Frank A. Hodson, contract surgeon, from Fort Mackenzie, Wyo., to San Francisco, en route for assignment in the Division of the Philippines.

Palmer H. Lyon, captain and asst.-surgeon, Vols., from temporary duty at Fort Hamilton, N. Y., to the Division of the Philippines via San Francisco.

Arthur W. McArthur, contract surgeon, from Fort Yates, N. D., to his home, Chillicothe, Mo., for annulment of contract.

Ben H. Metcalf, contract surgeon, now at Winthrop, Mass., to report for temporary duty at Fort Banks, Mass.

Charles E. Marrow, lieutenant and asst.-surgeon, U. S. A., former orders directing him to proceed to Fort Morgan, Ala., amended so as to require him to proceed to Fort Totten, N. Y.

William G. Miller, captain and asst.-surgeon, U. S. Vols., leave of absence from the Division of the Philippines extended one month.

Edward J. Morris, major and surgeon, U. S. A., from duty at the Model Camp, Angel Island, Cal., to the Division of the Philippines.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of a board of officers at Washington, D. C., to investigate and report upon a uniform size of packing boxes for transportation beyond the sea to secure ready handling and admit of packing securely in army wagons and upon pack animals, taking into consideration the contents of the boxes, weight, marking, etc.

Lorin B. Ohlinger, contract surgeon, leave of absence for one month granted.

Frank D. Pease, contract surgeon, now at Los Angeles, Cal., to proceed to Fort Mackenzie, Wyo., for duty.

Elias H. Porter, contract surgeon, relieved from duty in the Department of the East and on the expiration of his present leave of absence to proceed via San Francisco to the Division of the Philippines for assignment to duty.

John J. Reilly, lieutenant and asst.-surgeon, U. S. A., now at Fordham, N. Y., is relieved from further duty in the Division of the Philippines, and on the expiration of his present leave of absence will report for duty at Fort Slocum, N. Y.

Edwin W. Rich, lieutenant and asst.-surgeon, U. S. A., former orders directing him to report at San Francisco, for transportation to Manila, P. I., revoked; he will report for duty at the General Hospital, Presidio of San Francisco.

Charles Richard, major, surgeon, U. S. A., leave of absence for fifteen days granted.

A. H. Simonton, contract surgeon, leave of absence for two months granted.

John T. H. Slayter, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States.

Blair D. Taylor, major and surgeon, U. S. A., leave of absence extended ten days.

Samuel S. Turner, contract surgeon, from Fort Sheridan, Ill., to duty at Fort Yates, N. D.

William J. Wakeman, major and surgeon, U. S. A., on his arrival at the Presidio of San Francisco will report for duty at the Model Camp, Angel Island, Cal.

M. Manley Waterhouse, contract surgeon, from duty at Fort Wadsworth, N. Y., to Fort Hancock, N. J.

Francis A. Winter, captain and asst.-surgeon, U. S. A., member of an army retiring board at St. Louis, Mo.

Marshall W. Wood, major and surgeon, U. S. A., member of an army retiring board at St. Louis, Mo.

### Navy Changes.

Changes in the Medical Corps of the Navy, for the week ended February 15:

Surgeon L. W. Spratling, order to the Naval Hospital, Portsmouth, N. H., revoked; ordered to continue on waiting orders.

P. A. Surgeon E. V. Armstrong, detached from recruiting duty, February 17, and ordered to the *Olympia*.

P. A. Surgeon J. E. Page, ordered to Seattle, Wash., March 1, for temporary recruiting duty.

Rear-Admiral P. M. Rixey, commissioned Surgeon-General of the Navy and Chief of the Bureau of Medicine and Surgery, with the rank of rear admiral, from Feb. 10, 1902.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Feb. 13, 1902:

P. A. Surgeon Rupert Blue, to proceed to Des Moines, Iowa, for special temporary duty.

P. A. Surgeon E. K. Sprague, to assume command of the service at Detroit, Mich., relieving Surgeon J. J. Kinyoun.

P. A. Surgeon A. R. Thomas, to proceed to Liverpool, England, for special temporary duty.

A. A. Surgeon C. B. Sweeting, bureau letter of Jan. 16, 1902, granting leave of absence for five days from Jan. 23, 1902, amended so that said leave shall be effective from February 16.

Pharmacist F. L. Brown, granted leave of absence for ten days from February 10.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 14, 1902:

#### SMALLPOX—UNITED STATES.

District of Columbia: Washington, Jan. 25-Feb. 1, 2 cases.

California: Los Angeles, Jan. 25-Feb. 1, 7 cases; San Diego, Jan. 25, 1 case; San Francisco, Jan. 26-Feb. 2, 9 cases.

Illinois: Feb. 1-8, Belleville, 4 cases; Chicago, 2 cases; Danville, 2 cases; Freeport, 1 case; Galesburg, 1 case.

Indiana: Evansville, Jan. 25-Feb. 6, 13 cases; Indianapolis, Feb. 1-8, 23 cases.

Iowa: Clinton, Feb. 1-8, 3 cases; Ottumwa, Dec. 28-Feb. 1, 73 cases.

Kansas: Wichita, Feb. 1-8, 1 case.

Kentucky: Covington, Feb. 2-9, 3 cases; Lexington, Feb. 1-8, 3 cases.

Louisiana: New Orleans, Feb. 1-8, 3 cases.

Maryland: Baltimore, Feb. 1-8, 8 cases.

Massachusetts: Boston, Feb. 1-8, 54 cases, 7 deaths; Brockton, Feb. 1-8, 1 case; Cambridge, Feb. 1-8, 4 cases; Everett, Jan. 25-Feb. 8, 4 cases; Fall River, Feb. 1-8, 1 case; Holyoke, Feb. 1-8, 1 case; Lowell, Feb. 1-8, 4 cases; Malden, Feb. 1-8, 1 case; New Bedford, Feb. 1-8, 1 case; Newburyport, Jan. 25-Feb. 8, 3 cases; Somerville, Feb. 1-8, 1 case.

Michigan: Bay City, Jan. 25-Feb. 8, 12 cases; Detroit, Feb. 1-8, 6 cases; Ludington, Feb. 1-8, 2 cases.

Minnesota: Minneapolis, Jan. 25-Feb. 1, 18 cases.

Montana: Butte, Jan. 24-Feb. 2, 1 case.

Nebraska: Omaha, Feb. 1-8, 45 cases.

New Hampshire: Nashua, Feb. 1-8, 3 cases.

New Jersey: Camden, Feb. 1-8, 8 cases, 1 death; Jersey City, Feb. 2-9, 15 cases; Newark, Feb. 1-8, 33 cases, 7 deaths.

New York: Feb. 1-8, Binghamton, 1 case; New York, 61 cases, 10 deaths.

Ohio: Cincinnati, Jan. 31-Feb. 7, 12 cases; Cleveland, Feb. 1-8, 5 cases; Dayton, Feb. 1-8, 3 cases; Hamilton, Feb. 1-8, 3 cases; Toledo, Feb. 1-8, 2 cases.

Pennsylvania: Allegheny City, Feb. 1-8, 1 case; Norristown, Feb. 1-8, 1 case; Philadelphia, Feb. 1-8, 110 cases, 20 deaths; Pittsburg, Feb. 1-8, 1 case; Providence, Feb. 1-8, 1 case.

South Carolina: Charleston, Feb. 1-8, 3 cases; Greenville, Jan. 25-Feb. 8, 4 cases.

South Dakota: Sioux Falls, Feb. 1-8, 2 cases.

Tennessee: Feb. 1-8, Memphis, 15 cases; Nashville, 1 case.

Texas: Houston, Feb. 1-8, 32 cases, 2 deaths.

Washington: Tacoma, Jan. 24-Feb. 2, 20 cases.

Wisconsin: Fond du Lac, Feb. 1-8, 3 cases; Green Bay, Feb. 2-9, 19 cases, 1 death; Milwaukee, Feb. 1-8, 7 cases.

#### SMALLPOX—FOREIGN.

Austria: Budapest, Jan. 15-21, 11 cases; Prague, Jan. 11-18, 11 cases.

Belgium: Antwerp, Jan. 11-25, 6 cases, 1 death.

Brazil: Rio de Janeiro, Dec. 21-Jan. 12, 98 deaths.

Canada: Halifax, Jan. 25-Feb. 8, 3 cases; Quebec, Jan. 25-Feb. 3, 80 cases, 3 deaths; Winnipeg, Jan. 25-Feb. 1, 10 cases.

Colombia: Cartagena, Jan. 26, 2 deaths.

Great Britain: Liverpool, Jan. 19-25, 8 cases.

Italy: Naples, Jan. 18-25, 9 cases, 1 death; Rome, Dec. 16-21, 1 death.

Russia: Moscow, Jan. 4-18, 15 cases, 6 deaths; Odessa, Jan. 11-25, 13 cases, 3 deaths; St. Petersburg, Jan. 12-25, 12 cases, 3 deaths; Warsaw, Jan. 4-11, 2 deaths.

Spain: Corunna, Jan. 18-25, 1 death.

Uruguay: Montevideo, Dec. 28-Jan. 4, 77 cases, 4 deaths.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, Dec. 21-Jan. 12, 15 deaths.

Mexico: Vera Cruz, Jan. 25-Feb. 1, 1 case, 1 death.

#### CHOLERA.

Java: Batavia, Dec. 7-14, 3 cases.

Straits Settlements: Singapore, Dec. 21-28, 1 case.

#### PLAGUE—INSULAR.

Hawaii: Honolulu, Jan. 23-24, 2 cases; Kauai, Eleele, Jan. 22-26, 3 cases.

#### PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Jan. 4-12, 8 deaths.

## Address.

### THE NEW ERA IN MEDICINE—WHAT IT MEANS TO CLEVELAND.\*

P. MAXWELL FOSHAY, M.D.

CLEVELAND, OHIO.

Before taking up for consideration this Society, its relations, its ideals, its accomplishments and its future prospects, it will be necessary to my purpose first to secure a broad view of our present duty by widening our horizon to the extent of clearly apprehending some, at least, of the present conditions of professional life in America.

#### THE NEW ERA IN MEDICINE.

At the risk of tiring you with a partial repetition of ideas that have been expressed elsewhere, but feeling that it is justified by its inherent importance, I earnestly urge you to recognize the fact that we are living in a new era of medicine. The change from past conditions has occurred so gradually, when compared to the span of one active life, that the transition has in large part escaped our notice. It is, however, of the utmost importance that we at once realize its full significance, in order that time may not longer be lost in taking advantage of new and fruitful opportunities. The change to which I refer, when considered as a phase of the history of medicine, seems almost cataclysmal. Evolution in Nature and in society at certain periods moves with astonishing rapidity after long intervals of rest. Within a generation the science of medicine has been born, and the art and practice have been recreated. To-day we are living in the midst of the process, yet it is sufficiently far advanced for us to understand something of its meaning and profitably to reflect upon the goal toward which we are developing.

Coördinate with and in consequence of the tremendous development of the natural sciences during the nineteenth century, medicine has become rational. Adapting the scientific method and appropriating much of the knowledge accumulated by the pioneers in the natural sciences, medicine has finally and completely thrown off the heavy shackles of empiricism, of dogma, and of a narrow unreason. Medicine has arisen from the domain of empiric art to a fixed position among the applied sciences. True, medical science while thus correctly characterized has not yet reached the stage of completeness required for the passive extinction of the last remnants of medical superstition, ignorance, and bigotry. The world does not yet apprehend the full significance of the change, and we yet have Eddyism,

Dowieism, and a host of dishonest or misguided "isms" and "pathies." I do not agree with those who assert that these evidences of popular ignorance will continue so long as human nature remains unchanged. To do so is to disregard all the evidences supplied by the history of the development of knowledge. To hold this pessimistic belief is the same as it would have been in the Middle Ages to have asserted that the world in general would never know the paths of the planets, or the mass of the sun, or the law of gravitation, or the cause of the tides, or the circulation of the blood, or a hundred other truths which are so self-evident to the layman of to-day that he hardly realizes that they ever were unknown.

The medical profession, much less the layman, has not yet fully accustoming itself to its new environment of exact fundamental knowledge. Only the youngest among us have had the advantage of scientific educations. A distressingly large proportion of us still practice medicine very nearly with the same mental attitude as did our forefathers in medicine, who had none of the invaluable helps that have come to us through the growth of physiology, of pathology, of bacteriology, of pharmacology. Present students of medicine are being trained in accordance with the scientific method. In another generation they will constitute the profession of medicine. Shall we believe that the public will learn nothing from its intimate contact everywhere with these trained men? Has such a thing ever happened before? Never! Under such circumstances the people at large under modern conditions very promptly grasp much of the real significance of things. The hopelessly ignorant and the defective will, indeed, always be with us, but I am absolutely confident that in only a generation or two public opinion will have assimilated the broad conclusions of rational medicine, as it has the results of the evolution of all the sciences; and that general support for quacks, pretenders, faith-curists, and other preachers of the "isms" and "pathies" who depend for their success solely upon the ignorance of the public in relation to medical matters, will become absolutely impossible in civilized countries. To hold any other belief is to maintain that medicine is exempt from the natural laws of sociologic evolution. Such a supposition is postposterous.

#### THE FUTURE OF MEDICAL POLITY.

Medicine is every day gaining slowly and imperceptibly in public esteem. Our cessation of unseemly quarrels, our abandoning the discussion of dogmas, our devotion to the pursuit of real knowledge, our recognition from the workers in pure science, our common-sense methods, our rational attitude, are daily making a deep and permanent impress upon the minds of the educated

\* Inaugural Address of the President of the Cleveland Medical Society, January 24, 1902.

portion of the public. The rest will follow as day follows night. The conclusion, then, is easy that medicine in the future is destined to play an increasingly large part in public affairs. Of this I do not admit the shadow of doubt. It is our present duty adequately to prepare ourselves for our new functions in the body politic. Day by day there come into our possession facts and generalizations which are of comparatively slight importance to each of us in his daily routine, but which possess the most intimate relations to the welfare of the whole commonwealth. In the protection of the public health, considered in its widest significance, medicine of the future is surely destined to play a first part in general polity. In the very nature of things it can not be otherwise. To a very considerable extent we are now ready to assume this burden, but as yet the community only faintly realizes the value to itself of the knowledge which we possess and which we are constantly increasing and defining. It is then our present duty to undertake the education of the public. This can be accomplished solely through the powerful voice of perfected medical organization, aided by the instruction in rationalism that the active physician can give to his clients as they come and go.

#### RIISING PROFESSIONAL STANDARDS AND INFLUENCE.

The work has been begun. Having perfected the methods of medical education we have forced the states to demand that all who intend to practice medicine shall have been properly educated. We have insisted that the state shall itself determine the qualification of physicians, rather than to leave it to our schools. Further, we have everywhere placed upon the statute-books laws regulating the care of cases of contagious or communicable disease, and laws for many other purposes connected with the protection of the public health. These have a most distinct educational value in creating a more healthy public sentiment toward sanitary control. The elimination of the more or less empiric and irregular and generally-disqualified practitioners of the past, which is a steadily proceeding development, accompanied by the infiltration throughout the community of the younger and more scientifically educated practitioners, is producing a marked and healthy change in the public mind. Perhaps many of you think this too roseate a view. But look at the occurrences in this city among those whom we formerly regarded as irregulars. Look at the present status of the newest medical delusion; its exponents by actual observation are unable to remain more than six months or so in any one locality, unless in case of the great cities where the pabulum is in larger quantity. Of the apostles of this Still delusion there are fewer to-day in Ohio than there were a year ago. Former fads were not so readily eliminated. It is clear that it is becoming increasingly difficult to "work" the public, although far too easy yet to quiet all sense of recrudescence danger.

I need only mention it in order to recall to your mind the infinite improvement in the methods of medical education which so prominently mark the advent of the new school of medicine. Think of the facilities now required to teach medicine; the paid teachers, the laboratories, the instruments of precision, the well-organized hospitals and clinics. To teach medicine to-day is indeed a formidable task; only a generation ago it was the recreation of the teacher. Rhetoric has been displaced by science. The schools that give evidence of future permanence have of necessity become departments of the universities. The school privately owned by the

faculty is henceforth impossible. The spirit of university life and culture will forever hereafter be a powerful influence in medical training.

#### MEDICINE NOW A SCIENCE AS WELL AS AN ART.

The new school of medicine naturally divides itself into two or three broad departments. In the first place we find a line between the art and the science of medicine. Included in the science of medicine we find such well-recognized sciences as physiology, anatomy, pathology, bacteriology and hygiene. It seeks definitely to determine the cause and course of disease, and to know the exact mechanism of the reaction of the organism to remedial agents. The art of medicine on the other hand is concerned with the application of this coördinated knowledge to the study, the prevention, and the alleviation of concrete instances of disease. Within the art of medicine we find therapeutics, including surgery and its branches, physical diagnosis, and the larger part of the subjects grouped under the title "practice of medicine." Most of us necessarily are concerned solely with our art, but the science is at once the distinguishing feature of the new school of medicine and the indispensable and imperishable basis of our art.

#### PUBLIC MEDICINE.

Medicine may from another view-point be divided conveniently into two departments. The first deals with the individual instance of disease, the second with the health problems that concern the community as a whole. Improved educational methods are constantly perfecting our equipment for treating the individual. Up to the present we have been very halting in our methods of dealing with the problems of public medicine. These problems are daily growing in number and importance, and it is imperative that we should be prepared to meet them so fairly, so strongly, and so unanimously that we will gain the public respect and the satisfaction of having done our full duty. This can only be accomplished through our associating ourselves together so generally and so firmly that we will become a power in political affairs in so far as they may relate to medicine.

#### AN ERA OF GOOD FEELING.

The new school of medicine possesses one characteristic feature which stands out prominently and in marked contrast to the background formed by its antecedents. Professional progress has so often, indeed so usually, been retarded, even for a time arrested, by internal jealousies, personal quarrels, and the conflict of schools and cliques, that we should rejoice when we see about us so many evidences that physicians now view their professional conduct in a broader light, recognizing the desirability, the necessity, and the pleasure of maintaining cordial relations with all their fellows. Progress in this direction is by no means complete, and the chief agency in its steady promotion is the well-conducted medical society. More than all else we need to know each other and to be forced frequently to associate together. Often a few moments devoted to frank and hearty discussion of one of the unfortunate accidents of practice will make mutually respecting men of two doctors who, cherishing their misapprehension of each other, would otherwise drift into outspoken and lifelong enmity. Not seldom the social session of a medical society clears up long-standing disputes. This function of medical societies is not the least important, for unity of purpose and action inevitably develop from the establishment of harmony. Indeed, I think hardly any other one thing can be done by our profession which will so

promptly give us a high place in public esteem—an end much to be desired. Among the laity the disagreement of doctors has from time immemorial been the subject of levity. However, we have passed the turning point, and in this city even the laity has noted the change for the better. Perfected organization with its friendly association and its fraternal sharing of burdens is alone capable of continuing to its full fruition this happy tendency of modern medicine.

#### THE PUBLIC RELATIONS OF MEDICINE.

It is, however, principally of our present environment as affecting our own destinies and duties that I wish to speak now, and that is of the chiefest concern to each one of us here to-night. The fund of knowledge that has already accumulated as a result of the application to medicine of the scientific method is so vast that no one man pretends intimately to comprehend it all, and the possession of this trust inevitably brings with it power and responsibility. "Knowledge is power." Our knowledge may, must, be employed for the good of the whole world, as well as for the promotion of our own fortunes. The power that comes with it is all-sufficient to enable us to accomplish our full duty to the community. But we must each share in this responsibility, and stand ready to take up a part of the educated man's burden. Life is an opportunity to do good, to help our fellows, to leave the world a shade better than we found it, as well as a chance to secure some pleasure. He who misses the chief part of this opportunity loses that which above all else makes life worth living. The physician to-day has right to his hand an opportunity for rendering an illimitably beneficent service to his fellows which is far beyond that which comes to other men, because his knowledge closely affects the poignant problems of life, of health, of suffering, and of disease. This idea is not offered with any pretension of novelty. For at least a generation it has been repeated by thoughtful members of our profession. What I wish to make clear to-night is that never before has so favorable an opportunity been afforded us for actually doing that of which our forefathers in medicine dreamed.

#### PERFECTED ORGANIZATION.

No doubt some of you are tired of constantly having the benefits of perfected medical organization preached to you, but the importance of the subject is such that it may not be ignored. Medical organization is not a panacea for all the ills of mankind, nor a remedy for all existing defects in medical life. Effectively done, it will accomplish certain tasks to which our profession is pledged; pledged by the inexorable logic of events, not perhaps by voluntary expression on our part. Nor is the conception of the value of organization, of which you hear so much of late, a new one. The ground long since was thoroughly thought over by far-seeing minds amongst us. In all our recent discussion of this topic there is hardly a new idea. The real father of many of our ideas in this respect was Jerome Cochrane of Alabama, whose work was done under the difficult circumstances accompanying the "reconstruction period" in the Southern States. His writings during the early '70's breathe deeply of the spirit that now animates so many physicians throughout the Union. In his conception of the benefits of proper organization of the medical profession Cochrane has never been excelled for clearness of vision, force of presentation, or single-heartedness of speech and action. And the profession of Alabama has for 20 years been reaping the benefit.

while the rest of us, with only a few exceptions, have sat in disorder awaiting somebody to carry the news a few miles and to do our work for us. In 1875 Cochrane wrote: "We have no hesitation in saying that the medical profession is fully able to bring about a reformation of all the evils from which it suffers; but this consummation, most devoutly to be wished, can not be accomplished by wishing—can not be accomplished either by means of grandiloquent speeches and paper resolutions—can, indeed, be accomplished only in one way, namely: by wise and resolute work, and by thorough organization and concert of action among the members of the profession." Seven years later he urged the Alabama men "to seek always the public good and not our own, and always to recognize the great principle that union and organization involve strength and permanence and lead on from conquest to conquest, while the assertion of individual rights and privileges, and the gratification of personal jealousies and ambitions are always the agents of disintegration and defeat."

To-night the particular is of more importance than the general, and I will spare your patience by at once asking your consideration of conditions existing in this city and by suggesting some apparent present duties of this Society. And to begin with, I will recite some mild criticisms of ourselves that have come to me from different members, for it is well to conduct a careful self-examination before undertaking new duties.

#### BUSINESS TO BE DONE BY THE COUNCIL.

A number of the members object to the time now occupied in the early part of our meetings by the consideration of the business affairs of the Society. Under the rules some business goes to the Council for preliminary consideration. It might be well, however, to go one step further and entrust the final disposition of most of our business to the Council, as is done by many societies. I should heartily favor such an arrangement, if the majority of the members wish it. Our history shows that the men who comprise the Council have always been such as might be fully entrusted under proper rules to dispose finally of nearly all the routine and new business of the Society, even including the election of new members. When the first Constitution of the Society was drawn I made such a proposition, but it was agreed that the Society itself would wish to consider all its business in detail. I am sure that day has passed. In case such added duty is given to the Council, I earnestly suggest that the members of the Board of Trustees be added to the other officers who now compose the Council. The Trustees are elected for terms of three years so that this would tend to ensure continuity in the policy of the Society.

#### COMMITTEE WORK.

Of late years the Committees of the Society have not shown the interest and energy which would do so much toward making the Society really accomplish work of permanent value. This criticism falls chiefly on the standing committees, but not all special committees may escape. The Society appointed a Committee to investigate our public schools from a medical standpoint, which spent some time and some of the Society's money in collecting data that have not been reported on. The resolution appointing the Committee was specific in its instructions, and its report should have been of value to the whole community, so that it is a matter for general regret that after nearly two years the Committee has expired without making a report. I wish to add that

during the present year Committees which appear to be slighting their duties must not be disappointed to receive a request for their resignations. The interest of the Society is in such matters paramount to all other considerations. A medical society will be of service to the profession just in proportion as it is conducted along business-like lines such as apply to other organizations.

And here is a good place to state the truism that office in a medical society is an opportunity to serve the profession, and no one of us should accept a position unless fully prepared and determined to give to it enough of his time to successfully perform its duties. This indeed should be the chief clause in the creed of a medical society, whatever its scope.

There are those who criticise society methods but who rarely ever attend a meeting or make any endeavor to remedy defects of which they complain. On such critics rests the chief responsibility for every real fault that they see. Those who wish to see the Society do differently should show the honesty of their criticism by coming right here and giving their influence to promote the best interests of the Society. The stay-at-home critic is certainly not practical, and to all appearances he is lacking in candor. I am fairly familiar with medical societies, and I feel confident of my ground when I assert that there is no society which, having fallen into some undesirable habit, can not in a short time be completely rescued by the determined efforts of even one or two serious and unselfish men.

Other members do not come to our meetings because they have evening office-hours and have so many patients that they can not leave them two evenings in a month, even though others at least equally busy are among our most regular attendants. These absentees are themselves the chief sufferers, and were medicine a selfish calling we would simply say that those who thus deny themselves the educational influence of society work will themselves pay the penalty, as younger and better educated men, equipped with the most recent methods, slip ahead. But the spirit of our calling is more kindly, and so we wish to prevail on these men to turn out to our meetings and keep abreast of the times.

Some of the younger members say that they do not feel free to read or discuss papers and cases before other members who are older in the profession. This is a matter of determination. The physician who has the confidence in himself necessary to undertake the charge of a patient seriously ill should never hesitate to express his convictions on any subject with which he has had experience. The members must not overlook the fact that when they take part in the proceedings of the Society, even to a very small extent, they are sure to find afterwards that the salient points of the subject under discussion are much more firmly impressed on their memory than they would have been by merely listening to others. So I urge every member to take advantage of the opportunities offered for taking an active part in Society work. I think that if provision were made for the meeting between times of small numbers of the members to quietly discuss various topics, they would in this way very soon acquire sufficient readiness of speech to enable them to take part in the proceedings of the Society. A little later I will offer some specific suggestions as to means for meeting this demand, which is, I think, quite of first importance.

#### ORIGIN AND WORK OF THIS SOCIETY.

The birth of this Society on February 3, 1893, was

one of the early evidences of the liberal and progressive professional spirit which marks so distinctly the new era in medicine. Along with the application by physicians of the scientific method to the problems of physiology and pathology, and with the growth in medicine of the scientific spirit, there has come an appreciation of the catholicity of learning and of the brotherhood of knowledge. This Society was one of the first, and perhaps rather unconsciously, to mold itself according to the new conditions of professional thought and life. Arising to meet new conditions, and beginning without experience, the Society would have had to be superhuman to have wholly avoided mistakes in conduct, and as one of the early members I have no hesitation in admitting my full share in some of them. But having from its inception been guided by a clear aspiration to be of real service to the profession of Cleveland, the Society has profited by its errors, which have not been vital but merely incidental. I believe that it has been of definite service to the profession of this city. Were its only result to be found in the fact that it has brought about harmony in our professional relations, its existence would have been amply justified. But we all know that it has done a great deal more.

However, to-night it is chiefly to the future of the Society and of medicine in Cleveland that I would direct your attention. So far our work has been good, and in keeping with the spirit of the times, but progress is essential to the greatest usefulness in human affairs. We physicians of to-day are living in the most wonderful period of the history of medicine. Of this there is no shadow of doubt. Evolution in medical science and in professional thought is moving at a prodigious pace. We can not rest, or in but a moment we should be lost in the past. All over the United States thoughtful physicians are realizing that the time has come for the complete organization of the medical profession, in order that the commonwealth may receive to the fullest extent those real and great blessings which medical science is now prepared to offer and which will yearly, almost daily, increase in number and value.

#### TIME TO FURTHER PERFECT OUR ORGANIZATION.

What, then, can we physicians of Cleveland do to meet the ever-changing conditions of our professional life? I firmly believe that the time is now ripe for a further regeneration of our scheme of organization. I believe that it is now possible, indeed imperative, that we should organize ourselves on a still broader basis that shall give the opportunity to extend to a greater number of physicians the well-recognized benefits of society work, and to grant to the community the greatest usefulness of which we are now capable. I speak from some knowledge of professional conditions of other American cities when I say that I believe there is no other city in America in which the conditions are more favorable for working out to their fullest extent the possibilities for public service that are comprised in modern medicine. In other words, I believe that we medical men of Cleveland have to-day at our hands the opportunity of leading the way in demonstrating to the people and to the profession of this country just what of good can be accomplished by an organization of physicians thoroughly imbued with the high ideals and fully equipped with the perfected tools of the new school of medicine. Shall we allow our opportunity to slip by only to be seized by our confrères of some other community? I hope not.

## EXISTING MEDICAL INSTITUTIONS OF CLEVELAND.

Let us look at our materials. We have here in Cleveland excellent institutions for teaching medicine and for caring for the sick. We have an earnest group of men thoroughly in touch with the activities, ideals, and practical worth of scientific medicine. We have a most excellent beginning for a first-class medical library. We have two good medical societies doing creditable scientific work, each in its organic law assuming to represent the medical thought of the city. We have two good medical journals whose reputation for cleanness of conduct is second to none in the United States, and they are wholly controlled by physicians. Plans are matured for merging these two publications into one journal that shall be owned and controlled by the profession of this city, and which hence will be thoroughly representative of the best that Cleveland can do for medical science and for medical polity. The amalgamation of these two journals into one active and clean publication, which shall in effect be one of the distinctive professional institutions of Cleveland, marks a tremendous step forward.

## NEED FOR CONCENTRATION.

This, then, is a list of our tools. What shall we do with them? The suggestions as to how we shall answer this question are not original. The aim of the hour in medicine, as well as in all other progressive departments of human activity, is concentration and consolidation. The medical journals of Cleveland have met the demand. The hospitals in the nature of things are apart from this tendency. Most of us wish that for the greater prestige of the Cleveland profession the colleges were united, but that is a difficult problem, and one which is not for us to discuss to-night. We can only say that the schools are in good hands and that when the conditions for union become favorable, if they do, and we hope they will, those in control will meet the task in a frank, manly, and willing spirit. The scientific workers among us stand ready to assume their full share of the responsibility that naturally falls to them under the new order of things. The medical library provides an opportunity for the study of nearly all the best recent literature of medicine. The library is controlled by an independent association, has some permanent endowment, and owns the building in which it is housed. Its condition is highly encouraging. What concerns our purpose to-night is that the library needs a closer relation to the medical societies and to the profession as a whole. I think that our Society should set apart each year a fixed amount or percentage of its revenue to be added to the library endowment or used for whatever other library purpose seems most suitable. If sections or small subsidiary societies are arranged for, they should meet at the library. Its rooms furnish an ideal place of assembly for small society or section meetings to consider problems not yet ready for formal presentation to the whole profession and to clarify thought by the rapid and informal conversational method which is so effective. The time has come when gradually as need arises such groups should be formed and cordially supported by the representative medical organization. I believe that that society does the most good which reaches the greatest number of physicians, and so the most useful society in a city is the largest, but there is admittedly a very important function to be served by smaller groups which meet informally and perhaps oftener. To this I shall refer more specifically later.

## UNITE OUR PRESENT SOCIETIES.

There now remains for discussion this evening the chief topic in immediate importance. Every one of you I doubt not guesses it readily. Of course, it is that of the union of our two medical societies into one new organization of enlarged scope, of broad foundations, of high ideals, of absolutely representative character, in line of thorough equipment, so far as is now possible, for the work of the future. Some of you perhaps believe it to be impossible, unwise, and unnecessary; but my friends, it is easy of accomplishment if we will, and if we appreciate our new duties. It is, I am sure, the wisest thing that we can do, and above all I wish to impress upon you that under present and future conditions it is absolutely necessary. It is demanded by the steady processes of professional evolution, and if we now ignore this demand we shall for many years suffer the penalty that comes inevitably to those who ignore an opportunity for growth—namely, stagnation or even retrogression. Further, this much-to-be-desired end can now be attained without the least necessary sacrifice of any of the cherished methods of either present organization. A new organization started upon a proper basis can readily be devised to continue all the good features of the present societies and also to inaugurate and conduct to a successful issue many new undertakings for which there is now a real need.

## REASONS FOR UNION

First, as to the present necessity for this union. As you undoubtedly know, the American Medical Association has asked every State Society to re-organize itself upon one definite and suggested plan. It is difficult to see how our own State Society can ignore the request, and still more difficult to imagine any adequate reason for a refusal to comply with it. As other States are already heartily complying, and as our own State Society has a committee appointed to formulate the new plan of organization for presentation at its next meeting, it is certainly not assuming too much to take it for granted that it will follow the other States. This plan of organization is perfectly simple, and merely puts into effect in the common affairs of the medical profession the well-recognized American principles and forms of representative government. Already the American Medical Association has delegated all its business affairs to a body of less than 150 men in an association now numbering over 12,000 members. These delegates are to be elected by the various State Societies in proper ratio to their membership. The State Societies are asked to adopt a similar form, and in many the work is done. In one—Connecticut—this form of professional government has been in successful operation for over 100 years.

In putting it into execution in a State the plan of course will be for the state organization to turn over its business affairs to a body of delegates elected from the county societies. Of course, in any scheme of general organization some common unit is necessary, and by general consent the county medical society, as at present existing in all parts of the country, is recognized as the most useful and most readily available unit. It follows from these premises, then, as a necessary conclusion, that only one representative and affiliated society may be recognized in each county. As a necessary corollary to this it follows that, except under most extraordinary circumstances, no new society can arise to challenge this recognition. The new order of things has the element of permanence. In those counties which include large

cities this will in some instances for a time produce friction, though not in Boston, New York, Philadelphia, Baltimore, Cincinnati, or Chicago. Cincinnati deserves especial mention because she is our near neighbor and in our own state. Only a few years ago there existed there side by side the Cincinnati Medical Society and the Hamilton County Medical Society, a situation exactly analogous to ours at present, but with little difficulty they were both merged into the Cincinnati Academy of Medicine which now has a larger membership than had the two separate societies before the amalgamation. The lesson in this to us is direct and near to hand, the result has in every way been beneficial to the profession of Cincinnati, and our confrères in that city are fully prepared for the improved mode of organization. In Chicago, Cook County is represented by the Chicago Medical Society with its 1000 or 1100 members and its numerous correlated societies. I have already spoken of the undoubted benefits of small groups of medical men meeting quietly and informally to discuss those topics in which they are especially interested, and in which many others are little if at all concerned. So in Chicago they have a number of special societies, but each one requires that a physician to be eligible for membership must first be a member of the Chicago Medical Society. This provides adequate machinery for representative government, and places all the business interests of the profession in the care of one large representative society.

In the concrete, then, my suggestion is that we unite the Cleveland Medical Society and the Cuyahoga County Medical Society in a new organization to be known as the Cleveland Academy of Medicine, whose organic law shall be of the broadest and most liberal type, and whose aim shall be to forward the work of scientific medicine in Cleveland, to care for the material interests of the profession and to assist the community whenever the opportunity arises for the application to public affairs of the results of medical science. Those who are particularly and rightly attached to the small, informal, and quiet methods of the county society can at will meet their wants by organizing themselves into sections, societies, or clubs, whose membership shall be drawn from the membership of the Academy. This latter provision is necessary to preserve the representative functions of the Academy, and to enable us to turn upon the public the full force of our numbers, when occasion arises.

#### METHOD OF PROCEDURE.

To be specific, I recommend that the Society authorize the appointment of a committee of five whose duty it shall be to meet with a like committee from the County Society for the purpose of considering, outlining, and recommending a plan of union. As a preliminary the Secretary should be instructed to communicate with the County Society in order to first learn whether it is agreeable to that organization to receive our overtures. These negotiations should be conducted solely in the spirit of doing that which is best for medicine in Cleveland. In such a laudable undertaking both organizations should be willing to yield a point whenever necessary. As a matter of fact their methods of organization are so similar that little sacrifice will be necessary on either hand. Let us, then, at once approach this enterprise with a determination again to improve the status of medicine in Cleveland.

#### CONDITIONS TO BE MET BY THE NEW ORGANIZATION.

At present the Cleveland Medical Society meets twice

a month from September to June inclusive, holding 20 meetings in a year, several of which are devoted to addresses by invited guests. The County Society meets once a month, holding 10 or 12 meetings a year. The programs of both organizations are kept well filled, and it would, I think, be detrimental to permit the consolidation of the societies to permanently reduce the number of medical meetings held in this city during a year. Therefore, in case the union is effected, as I earnestly hope, I recommend that at once a subsidiary clinical society shall be organized which shall hold its meetings at the library, thus at once replacing the good scientific work of the County Society, providing for a quiet society for free and informal discussion, and furnishing an attraction to draw more men to the library. This subsidiary society should in every respect be free from the control of the Academy, except that it should receive no members who are not members of the Academy. Other subsidiary societies can be organized on the same plan and with the same meeting-place, whenever the need arises. The time has come when we must recognize the fact that one large medical society with bi-weekly meetings does not meet all the needs of our medical community. The meetings of the County Medical Society once a month, while of distinct and unquestionable value, do not provide fully for the deficiency. Nor is the reason for this state of affairs far to seek. As a result of the rapid and tremendous accumulation of medical knowledge during the past generation no one of us is able to cover the whole field either in practice or in study. In consequence each of us can not any longer be expected to have a direct interest in each of the few phases of our knowledge that can be dealt with at the 30 medical meetings held in this city during the year. So we find that many men do not attend our meetings regularly because they say the programs do not present subjects in which they are specially interested. Under present conditions the result can not be otherwise. Therefore when urging a union of our two societies it is necessary to at once suggest an elastic system whereby as need arises new but closely related bodies may be formed on demand.

There are at present in this city two small independent medical societies which, in case of our executing this scheme of centralization of interest, should be invited to attach themselves to the general body by the simple and sole bond of requiring their members to belong to the proposed Academy.

#### EXECUTIVE FUNCTIONS.

The new Society might well consider some change in the functions of its officers. At present in this Society the President is the sole executive head and upon him rests the greater part of the responsibility for the successful working of the organization. This being the case it is essential for our welfare to elect as President men who will heartily interest themselves in its work and who will not hesitate to sacrifice their own interests for the Society. There are many times, however, when the members feel that it would be a graceful compliment to bestow the presiding function upon a member who has passed the period of chief activity. Under present conditions this can not be done without risking the welfare of the organization. Therefore it is possible that it would be wise to create another office, or to so enlarge some present one, that the business part of the President's duty could be placed on other shoulders. In pursuance of this idea, the New York State Medical Association now employs a lay business manager.

## PERMANENCE OF METHODS.

Another valuable feature that should be introduced by such a new organization would be a permanent assistant secretary, paid a small stipend for seeing to the printing and mailing of the programs and other notices. This would ensure permanency of system. Such an assistant Secretary might well be the resident librarian at the Medical Library. The regular Secretary could then keep the minutes and have a general oversight of the work.

## A REFERENDUM.

In considering improvements for the future it has occurred to me that perhaps the membership would be better satisfied with the conduct of the Society if in electing officers or in voting on an amendment a referendum were provided for by having ballots sent to every member, so that he can vote by mail. This would ensure to each one his franchise, and not leave the determination of such questions merely to those who happen to be in attendance. This I make as a suggestion, rather than as a recommendation. The same method is in satisfactory operation in a number of non-medical societies. The necessary machinery is simple, and our Society can readily adopt the method if it seems desirable.

## NEED TO INCREASE MEMBERSHIP.

Our Society should at once undertake an active and systematic canvass for new members. In this county there are over 800 regular physicians and we in both our present societies include but 265. Many more must be brought into our borders and made welcome. I shall urge our Committee on Growth and Prosperity to district the city, call for volunteer aids, and solicit every possible member. In this connection we should not forget how far ahead of us some other cities are. For instance, the Cincinnati Academy of Medicine now has about 90 more members than our two societies together, not counting our duplicated members. We certainly must not allow Cincinnati to maintain this lead that has followed her concentration of effort into one organization. The New York County Association each year issues a medical directory of the city. This is, of course, of the greatest service in the work of organization and also of enforcing the laws. If we wish, we can just as well have a directory of our own in Cleveland. This would enable us to follow the irregulars, as well as to furnish material for a canvass for new members.

## SOCIAL FEATURES.

An unscientific, unpolitical, but still really important part of medical society work remains to be considered. The marked success and value of such a social evening as we spent together last week suggested to all of us that such events should not be so uncommon. The very greatest good surely follows such evenings of social intercourse. Some provision should in the future be made for having assemblies of somewhat similar character once a quarter if possible. Or we might imitate the successful example of the Chamber of Commerce in dividing its meetings into two parts, separated by a twenty-minute interval during which light refreshments are served. On the whole I prefer the quarterly social evening, and I suggest that if it is adopted provision should be made for holding it on some other than a regular meeting night, so as not to reduce the number of scientific meetings in a year.

## OUR AIM.

Gentlemen, I see nothing in the way of our undertaking to make Cleveland a model city in respect to its

sanitary condition. With our enthusiastic and capable health officer supported by a united profession we can very readily not alone equal the health conditions of other cities but actually take the lead. While I have taken largely of your time in outlining how this may be accomplished, I have left much unsaid that will occur to your minds as following naturally from the perfection of an active medical organization. Further than this we can, by all pulling together, put Cleveland up among the very first rank of cities in respect to the quality of medical work done. We can become a widely known medical center if we will. True, the quantity of our work will fall below that of larger cities, but there is not the least need for this to apply to the quality. Our laboratories, hospitals, colleges, and the workers are now available. A medical journal on the broadest possible foundation is now provided for. A large representative society with subsidiary sections or societies which shall continue more carefully to cultivate the highest type of research and clinical study, and shall lay its results before the world in the journal, will supply the remaining factor necessary to making Cleveland a widely known medical center. In making this our ambition none of us has anything to lose, and it seems to me that every one has something to gain. Let us heartily and in fraternal spirit determine to do this thing. If we do, the deed is done. The time is propitious. I can not imagine that the present opportunity will long remain with us, or that it will soon recur.

Lastly, let us make our medical society as nearly an ideal one as is attainable. Even now our Society is held up as an example of successful society work, but we can do so much more. Above all our other ambitions let us bear in mind that the most essential feature of our organized life must ever be its harmony. We must bring within our fold every available physician in Cleveland and then let us dwell together in the spirit of science, in the spirit of mutual courtesy, in the spirit of true brotherhood, and above all in the spirit of peace.

[N. B. Since this address was delivered both societies have unanimously accepted the principle of union and have appointed committees to arrange details.]

## EXTRA-UTERINE PREGNANCY.

F. F. LAWRENCE, M.D., D.Sc.

Clinical Lecturer on Diseases of Women and Abdominal Surgery,  
Starling Medical College,  
COLUMBUS, OHIO.

To those who have looked upon a ruptured tubal pregnancy, I need not attempt to paint in words the picture of this terrible complication. That the surgeon is still so frequently called upon after a tubal pregnancy has ruptured and the patient is exsanguinated, all too forcibly emphasizes the fact that the importance of this subject has not yet been fully grasped by our obstetric teachers. That it is practical to diagnose the condition before rupture has been demonstrated so thoroughly that if the medical profession were fully awake to the needs of the hour very few of these cases would ever reach the stage of rupture. In 1892 I made the diagnosis before rupture—which operation verified—of extra-uterine pregnancy, and, since that time, have diagnosed this condition no less than nineteen times before rupture. I have always considered that the diagnosis

could be made, and was unaware that it was not a usual routine among men competent to rank as abdominal surgeons, until a few months since a paper was published upon the subject, in which it was claimed to be something unusual.

As a rule the diagnosis before rupture is easier than it is after the rupture and its accompanying hemorrhage have resulted in peritonitis. The fact is becoming increasingly apparent that extra-uterine pregnancy occurs much more frequently than has been supposed. A few years ago it was considered a very rare experience for one surgeon to see more than two or three cases in as many years. Now there are very few men of any experience in abdominal surgery but that have had more than one series of two or three cases in one week. The importance of this from an obstetric standpoint can not be overestimated. It should lead to an emphatic demand for early and thorough examination of every woman supposed to be pregnant—aye, more, it should lead to such obstetric education as will cause every woman to look with suspicion upon any and every irregularity of menstruation and prompt her to seek competent advice.

This course will result in the diagnosis of practically all cases before rupture, or at least an opportunity for the diagnosis to be made. It might be said here that a reformation in methods of teaching, which will make diagnosis and pathology paramount to operative clinics, would result in greater diagnostic acumen, a healthier view of the responsibilities involved in abdominal surgery, and fewer attempts to mount the ladder of fame with woman's abdomen forming the first round.

It is a sad reflection upon the scientific spirit which pervades our profession to note that in many of the medical colleges, the chairs of obstetrics, gynecology and also that of diseases of children are filled by such material as can be secured regardless of past experience, training, or special preparation. No man should attempt to teach obstetrics who is not competent to make the diagnosis of extra-uterine pregnancy, either before or after rupture, and then he should be able to teach his students how to do the same thing.

A safe rule in the surgery of the uterus is to regard every enlargement of the uterus as suspicious of pregnancy until that is positively known not to exist. I should like to add that I believe an equally safe and valuable rule is to look upon every woman who has the opportunity of pregnancy, as a probable victim of extra-uterine form, and, if she presents the slightest irregularity of menstruation, institute a thorough examination of the tubes. The history of the patient should be carefully and thoroughly taken. This will develop the fact that she has at some time in the past had some form of tubal disease. This has been found to be true in every one of my cases, now numbering thirty-one.

This is one thing upon which there may be some difference of opinion based upon different interpretation of the signs and symptoms of tubal disease, but if close inquiry be made it will be found that the patient has suffered premenstrual pain to a greater or less extent. The menstrual flow has been irregular both as to amount and duration. In some cases she will give a history of a severe attack of pelvic inflammation at some time. There will be a history of leucorrhea, irritable bladder, and in some cases rectal tenesmus. Then will follow an ordinary menstruation, which did not stop in the usual number of days, but there was a "little flow" right along for one, two or three weeks. During this time there has been an increasing feeling of discomfort in the pelvis.

There has been irregular but frequent pains through one or other side of pelvis, irritability of bladder and rectum with painful defecation. She is frequently found to be apprehensive of some unexplainable calamity impending. The breasts have developed the usual condition of pregnancy, but in a more rapid manner than usual.

In some cases there has been a long interval between this and the last pregnancy, but this is a very unreliable indication, as I have had two recent cases in women who had given birth to children within eleven months and fourteen days, and thirteen and one-half months respectively. Two years ago I operated upon a woman who was two and one-half months in tubal gestation, whom I had delivered at term only seven months previously.

The examination of a patient with the above symptomatology will reveal the following: 1. The conditions of vagina and uterus found in a normal pregnancy except that the uterus is hypersensitive. 2. To one side or behind the uterus will be found an elastic, sensitive, sometimes but not always, pulsating tumor. 3. There is one evidence found in extra-uterine pregnancy before rupture that I have never been able to find in any other condition; that is a peculiar elastic crepitation, not unlike that elicited by feeling the normal placenta when the membranes have been turned external. It is not the crepitation of blood clot, as is so well known to be present after rupture, but it is absolutely different and distinctive. 4. In nearly all cases the mass will be practically fixed, and, if a careful search be made, the ovary can be found in close proximity to the tumor, but still not a part of it. It has been said that the tumor of extra-uterine pregnancy is "only blood clot;" this is not the case before rupture. At this time the entire tumor consists of the enlarged tube, such placental tissue as can develop from tubal mucosa and the fetus itself. There has as yet been no hemorrhage, hence there could be no blood clot. If the above conditions be found, and, in addition, there is known to have been shreds of membrane in the menstrual discharge, or if this is shown to be so by microscopic examination, the chances of being correct in the diagnosis of extra-uterine pregnancy are about ninety-nine out of every one hundred cases.

I wish here to be understood thoroughly when I say I believe the diagnosis of this condition is practicable in the majority of cases and that it is due to the wives and mothers that we not only emphasize the frequency, importance and danger of the condition, but that we also emphasize that a failure to attempt to make a diagnosis before rupture when the opportunity for investigation is presented, and we do not examine with a view to diagnosis, is a failure totally without excuse, and one which, if the woman should die as a result of rupture and hemorrhage, would place a very heavy moral responsibility upon the shoulders of him who caused the delay by failure to recognize the condition. You may say this is harsh, but it is not so cruel as to stand by and say we must wait until the tube is ruptured and the woman's life in peril from both shock and hemorrhage, before we awake to the possibilities of her danger! Let us at once say, "The diagnosis can be made and we will do it." Then let us teach all our students as well as all others who wish to know, how to do this, and, when that has been done, men will see and feel not only the need of examining each patient carefully, but they will be proud to point to the many whose lives are and ever will be a proof that there is science in diagnosis.

Let us teach, not the technic of some new-fangled modification of some other man's operation, but teach men how to recognize this obstetric condition, and also

teach them that the diagnosis is greater from a life-saving standpoint than is the operation itself. Give the medical world to understand that an "exploratory incision" as a means of diagnosis is in all but very rare cases a course only resorted to by incompetents and cowards. The exploratory incision has and ever will have a proper and necessary place in abdominal surgery, but I am convinced that no other procedure has been so much misused, or so fatal in its results as this. The term would be better eliminated from our literature, if it is to continue, as in the past, to be the means whereby men without training, ability or conscience, shall cover their weakness, incompetence or mercenary characters. It is the duty of those whose work and study have rendered them competent to teach the world that true surgery is conservative, honest, scientific, safe and founded upon correct and accurate ideas of pathology and the conservative powers of nature. The medical profession and the laity have a right to demand of us sound and fearless teaching, thorough preparation, diagnostic acumen, as well as operative dexterity. The latter can not be acquired by all because opportunities for all to operate frequently can not be obtained, but the first three can be and should be the right and possession of every man.

The diagnosis after rupture has taken place will present the same history as already given, except that there has been a severe tearing pain, accompanied or followed by faintness, pallor, rapid pulse and all the other signs of hemorrhage. This sharp pain that has been considered almost an essential part of the case is by no means always so marked. Too much stress has been placed upon this symptom. Abdominal distension is rapid, and unless the patient dies as a direct result of hemorrhage, peritonitis is a very early complication. The vaginal and bimanual examinations are both extremely apt to add to the hemorrhage by displacing the clot, hence great gentleness and caution are necessary. The early occurrence of peritonitis renders the bimanual and vaginal examinations still more unsatisfactory. The tumor formed by the hemorrhage behind or to one side of the uterus is tender, and usually pulsating. If peritonitis be not present, gentle palpation will elicit the crepitation of a blood clot.

The history being as that outlined in diagnosis before rupture, these findings will be enough to determine that we have an extra-uterine pregnancy with which to deal. The choice of route by which to operate is to be determined by two factors: 1, the condition of the patient, and 2, the method in which the individual operator is most dexterous. It must always be borne in mind that these patients are, or have been as a rule, the subjects of tubal disease, hence while the primary object is to remove the extra-uterine pregnancy, an equally important object should be the safety from complications and accidents. It has never yet been my good fortune to see an extra-uterine gestation which was not more or less complicated by intestinal or other adhesions. Before rupture of the tube has occurred these adhesions form the greatest source of danger in the operation. The rapidity and safety with which they can be overcome through an abdominal incision, are in strong contrast with the uncertainty involved in a vaginal operation. After rupture has taken place clots may be found in the renal, or hepatic regions; in fact, in any place in abdominal cavity, even the fetus may be high up, as I have twice found it, once immediately under the transverse colon.

It is necessary to work rapidly and yet the work must

be thorough. These objects can best be accomplished through an abdominal incision, i. e., the prompt and efficient control of the hemorrhage, the cleansing of entire peritoneal cavity, and the safe separation of visceral or other adhesions. There is, however, one class of cases in which the hemorrhage has ceased, infection has taken place, followed by suppuration. In these cases the infection is of a very virulent type, and is the chief factor in the case, hence if the mass be low down and easily accessible, it should be incised and emptied through the vagina, no effort being made to separate adhesions or to remove the tube. Simply incise, drain and after the patient shall have recovered from the infection, the adhesions can be treated as the case may require. The idea that we should ever enter upon a vaginal operation which may present conditions requiring us to open the abdomen with haste in order to save our patient's life, seems to me one fraught with many possibilities for evil, and an idea it would be well to abandon.

Our responsibility for the teachings in our papers does not cease when the meetings are over; many men, both young and older, will be influenced more or less by what we here teach, and if I have seemed dogmatic in what I have written it is not from a spirit of dictatorial narrowness, but rather the earnest belief that the statements made are supported by pathology, clinical observation and logical deduction, and the desire to urge upon all who may hear or read what I have written, the importance of careful study and accurate diagnosis of our cases before we begin an operation, then perform the operation best suited to the case, be that abdominal or vaginal.

#### THE ROLE OF CERTAIN NON-GRANULAR AND GRANULAR SOMATIC CELLS IN INFECTION.

TECHNICS—THE ORIGIN, SIGNIFICANCE AND FATE OF THESE MORPHOLOGIC ELEMENTS.

H. F. HARRIS, M.D.

PROFESSOR OF PATHOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS. ATLANTA, GA.

It very rarely happens that these cells can be studied with advantage without proper fixation and staining. Indeed, with our present knowledge, it may be said that it is impossible to recognize some of them in the fresh state, and their study in this condition does not, therefore, seem of sufficient importance to take up any of our time on the present occasion.

Whenever we wish to make studies of cells it is always a matter of the highest importance that the tissues be as fresh as possible, since many of the more delicate morphologic constituents of these bodies immediately begin to undergo alteration following death, and this process continues until they undergo complete disintegration. Fortunately for us, however, in this connection it is as a rule the case that we are more particularly concerned with the protoplasmic portions of the cells, and as these do not undergo such rapid changes as those parts that go to make up the nuclei, it is not absolutely essential that the tissues should be so fresh as is necessary where studying the latter-named bodies; therefore, although it is axiomatic that tissues for accurate study should always be fresh, it is not infrequently possible to recognize these various cells even in tissues that have been dead for a considerable period before having been placed in the fixing solution.

It is unfortunately true that those fixing solutions which preserve nuclei best are not those well suited for

studying these cells, inasmuch as they interfere seriously with many microchemic reactions; and as it is upon these reactions that we largely depend to differentiate some of them, it is apparent that such solutions can not be employed for fixation with advantage.

Of the various fixing solutions that may be recommended for the study of these cells those mixtures containing corrosive sublimate are to be most highly recommended. The reason for this lies in the fact that most of the microchemic reactions which are of value in their study are obtained with aniline dyes belonging to the thionin group, and these stains possess the peculiar property of uniting with mercuric salts, producing compounds which are more brilliant in color than the dyes originally employed, and also that these newly formed substances cling to the tissues with much greater tenacity. It does not appear to be a matter of great importance which of the corrosive sublimate solutions are employed. Recently I have been in the habit of using the mixture of Bensley, which consists of equal parts of a saturated solution of bichlorid of mercury in alcohol and a 1 per cent. solution of bichromate of potassium in water. The only fault with this solution is that it has to be made fresh each time and can not be used over again. The fixation produced by it is very fine, and in addition to leaving the tissues in such a condition that the various microchemic reactions may be easily obtained, the several morphologic elements of the cells are preserved with great faithfulness. Zenker's solution, Foa's solution, and the various other solutions of bichlorid of mercury may be also employed, but for some reason that I can not explain those fixing fluids containing bichromate of potassium seem to act best.

Alcohol may be also used for hardening the tissues, but as it is impossible to obtain the brilliant microchemic reactions after its use that we get following corrosive sublimate, and as the morphologic constituents of the tissues are not so well preserved, it does not seem that there is any good reason for employing this reagent in a routine way for hardening.

Either celloidin or paraffin may be used for embedding the tissues, but on account of the fact that paraffin is much more convenient, that the tissues can be preserved in it indefinitely without injury, and, more than all, for the reason that much thinner sections can be cut when it is employed, it should always be given preference.

For staining the tissues various methods will have to be employed, depending upon what part of the cell it is especially desirable to investigate. When we wish to study the nuclei the various stains that are obtained from hematoxylin are to be particularly recommended—especially is this the case if the tissues be fixed in corrosive sublimate, for this substance and the hematoxylin derivations unite with each other with great readiness, forming dark purple compounds which are even more brilliant than those produced by this staining reagent alone. The iron hematoxylin methods are also of much service—that of Benda being especially convenient. When studying the microchemic peculiarities of these cells the aniline stains belonging to the thionin group are absolutely necessary. It is rather singular that microscopists, following the lead of Unna, have apparently without question assumed that alkaline solutions of these dyes are necessary for obtaining the various microchemic reactions which they are capable of producing, but as a matter of fact the staining effects are in every way as good when neutral solutions of these dyes are

used. Thionin, methylene blue, and toluidin blue will either of them, when employed in a simple aqueous solution, give these reactions in a perfectly characteristic way, but if they be dissolved in a 4 or 5 per cent. solution of carbolic acid in water, the staining effect is somewhat more brilliant and is produced with greater rapidity. After corrosive sublimate fixation it requires from ten to fifteen minutes for staining. Specimens from alcohol should be always washed in water before being placed in the staining solution, as a dirty precipitate otherwise often occurs; for the same reason a like precaution should be taken in cases where alcoholic solutions are employed to differentiate the stain. After rinsing in water the specimens should be washed in a weak acid solution of alcohol, or, what I think somewhat better, Unna's glycerin-ether mixture diluted 5 to 10 times with water; differentiation by either of these methods is brought about in a few minutes. The tissues are then thoroughly washed in alcohol, and cleared with cedar-wood oil, xylol, or chloroform. If the various procedures be carried out in the proper manner the chromatin of the nuclei of all cells is stained in varying shades of blue, depending upon the dye that is used; the granules in the so-called plasma cells (really fibroblasts) are colored a dark, purplish tint, and the granules in the mast cells assume a bright cherry-red color.

Eosin as a counter stain should be employed after hematein, or following toluidin-blue when it is desired to bring out the peculiarities of the protoplasm of eosinophilic cells and polymorphonuclear leucocytes.

As regards the origin, fate and significance of these morphologic elements, I thoroughly appreciate that we as yet possess little absolute knowledge; still the facts in our possession would seem to justify certain conclusions concerning them which make their further study a matter of great interest.

*Plasma Cells.*—In the light of more recent investigations the view first advanced by their discoverer, Unna, that these cells are produced from connective tissue by a process of direct division does not appear to be tenable, but, as was first maintained by von Marschalko,<sup>1</sup> it seems that there is little doubt that they are directly derived from lymphoid cells by an increase in their protoplasm, and by the formation around their nuclei of small, basophilic masses that are undoubtedly closely related to the prozymogens which have been discovered in the secreting epithelial cells of glandular organs, and, like them, probably the result of the migration of certain parts of the nuclei into the surrounding protoplasm. This brings up the exceedingly interesting question as to how the lymphoid cells that are so abundantly present in and around old inflamed areas reach these situations. True, it is maintained by many that these cells possess the power of ameboid movement, and hence it is assumed that they are capable of passing through the walls of the blood vessels just as do the polymorphonuclear leucocytes. It can not be denied that this may be true, but it does not appear to me altogether likely for the following reasons: In the first place in those inflammatory conditions where great numbers of polymorphonuclear leucocytes collect in the diseased parts there is never, in my experience, the proportion of lymphoid cells intermingled that occur in the blood. And in the second place, nothing is more familiar to every pathologist than the fact that in mild inflammatory conditions of a chronic kind enormous numbers of lymphoid cells may

1. Von Marschalko: Ueber die sog. Plasmazellen: ein Beitrag zur Kenntniss der entzündlichen Infiltrationzellen, Arch. f. Dermat. u. Syphilis, Bd. xxx, 1885; and also in Centralbl. f. Path. u. path. Anat., Bd. x, S. 841.

be massed together without any of the polymorphonuclear leucocytes being present at all—which certainly would not be the case if they all passed directly from the blood vessels. Of course it is conceivable that the different chemotactic substances may each have the power of attracting only one kind of leucocyte, but so far as I am aware we have no knowledge bearing directly upon the matter. For some years it has appeared to me that the explanation of these peculiar facts might lie in the possibility that the lymphoid cells reach the diseased parts by means of the lymphatics, and on account of the damaged condition of the walls of the lymph vessels, and the greater amount of pressure in the diseased parts the cells do not pass through, but accumulate in and around these areas. I have made a number of experiments in the attempt to prove this, but have not as yet reached any satisfactory results.

As regards the fate of these plasma cells it seems highly probable that they are the real fibroblasts—the collagenous tissue being formed by a process of secretion around their periphery. After a certain amount of fibrous tissue has been formed around them, they seem to be what are commonly, but erroneously, called fibroblasts. As cicatricial tissue develops these cells undergo retrogressive changes, break up, and the resulting debris is carried away by means of the lymphatics or by the phagocytes. This, however, does not always seem to be the fate of these cells, since a certain number of them become branched, their protoplasm loses its basophilic affinities, and the cells remain in the parts as fixed connective tissue cells. Under certain conditions it is not improbable that other alterations may occur in the cells, as a result of which they become hyaline, and, as von Marschalko<sup>2</sup> has recently claimed, in this condition may become the so-called cancer parasites of certain authors.

Concerning the significance of these cells, I should personally look upon them as always indicating the beginning formation of cicatricial tissue.

Perhaps the easiest and simplest method of demonstrating them is to stain in carbol-toluidin-blue for from 10 to 15 minutes, and to afterwards differentiate in Unna's glycerin-ether mixture. The cells may be recognized by the fact that they are rather large, and that there are numerous fine granules within them that are colored a very intense slaty blue by the dye, and that the cells are not uncommonly of a somewhat squarish form.

**Endothelial Cells.**—Concerning the new formation of these cells in disease, I must confess to complete ignorance. It appears, however, not improbable that they are never produced from other cellular constituents of the body, but, like epithelial cells—with which they appear to be identical—are only reproduced from pre-existing cells of their kind.

The endothelial cells may be easily demonstrated by any of the ordinary methods of staining.

**Eosinophilic Cells.**—The eosinophile cells are generally regarded as being old polymorphonuclear leucocytes. As regards the fate of these cells in infection, I possess no definite knowledge, but presume that when the infection is of a virulent kind they, along with the others present in the diseased area, undergo necrotic changes. I am not aware that their presence is of any significance in connection with infections.

These cells may be readily demonstrated by staining with hematoxylin and eosin, and although more elaborate methods may be employed, the results do not appear to

warrant the extra amount of trouble necessary in order to use them.

**Mast Cells.**—In the light of present knowledge it seems fairly certain that there are several different kinds of cells that have received this common appellation.

1. The mast cells of Ehrlich. These cells are found especially in the submucous tissues of the body, but may be found in any of the connective tissues except those of the brain, spinal cord and meninges; they are rather large, very irregularly shaped cells, and doubtless have the power of ameboid movement. They never contain more than one nucleus, which is quite homogeneous, and it takes basic dyes feebly. The protoplasm of these cells contains many large granules that give characteristic reactions with certain dyes.

2. The mast cell of the lymphatics. These cells are found in the lymph nodes of the lower animals, and under certain conditions in those of man, and differ from the mast cells just described in that they are smaller, and that they are, as a rule, more rounded in outline, that their nuclei are generally nearer the centers of the cells, and that their protoplasm contains but few granules.

3. The mast cell of the blood. These cells differ only from the cells just described in that their nuclei are oftentimes lobulated; when this is not the case the two cells appear identical.

4. The muscle-fiber mast cell. Around chronic lesions the protoplasm of involuntary muscle fibers sometimes undergo alterations as a result of which mast cell granules are formed. The change does not interfere with the morphologic peculiarities of the fiber in which the process occurs.

As I pointed out some time ago,<sup>3</sup> the granules that are present within these cells stain with Mayer's muchematein, as well as with other specific stains for mucin, and they therefore appear to be made up of mucin or some substance very closely related to it. I have suggested that the name *mucinoblast* should be substituted for the entirely misleading word, mast cell.

As regards the origin of the first three of these cells we are still, more or less, in the dark. It would appear not improbable that the mast cell of Ehrlich is derived from either the large phagocyte of Metchnikoff, or from cells that are nearly related to them, though there is, so far as I am aware, no definite proof of this. Those mast cells occurring in the lymph nodes appear to have been derived from hyaline cells that themselves very closely resemble the large phagocytes just referred to, and the mast cell of the blood seems undoubtedly to take its origin from the large hyaline cells that are present to a limited extent in this fluid.

There can be no question that these cells, both in health and in disease, in the course of time undergo degenerative changes, break up and entirely disappear; this process is particularly active under the latter condition. When the large intestines of dogs are subjected to some powerful irritants the mast cells, even deep down in the walls of the gut, disappear with remarkable rapidity, and there can be no doubt that under these circumstances they break up, and that their granules undergo solution. As the result of recent investigations, I am strongly disposed to think that the granules from these mast cells sometimes pass directly through the basement membranes, and become included in the bodies of the mucin-bearing epithelial cells; the granules then become united with the constituents of the protoplasm of the

2. Von Marschalko: Die Plasmazellen im Rhinoscleromgewebe, etc. Arch. f. Derm. u. Syph., 1900, Bd., 54, Heft 2 u. 3.

3. Harris: Histology and Microchemic Reactions of Some Cells to Aniline Dyes, Phil. Med. Jour., April 7, 1900.

cells, and give rise to the substance that we call mucin. Concerning the mechanism by which this is brought about, I hope to be able to speak in a future communication.

Inasmuch as these cells have a tendency to disappear in acute inflammatory conditions their absence under these circumstances is of more or less significance, but in chronic processes they not infrequently considerably increase in number, and their presence under these circumstances may be suggestive of the character of the condition. This peculiarity seems to be of especial importance in differentiating so-called inflammatory conditions from sarcoma.

There are many methods of demonstrating these cells, but perhaps the most satisfactory is to stain for a short time in carbol-toluidin-blue, and afterwards to differentiate in Unna's glycerin-ether mixture. These cells after being stained in this way may be always readily differentiated by the fact that the granules contained within them take on a peculiar cherry-red tint, to which reference has already been made in this paper. As has been before remarked, they stain intensely in Mayer's muchematein.

#### THE CORRECTION OF DEFLECTIONS OF THE NASAL SEPTUM WITH A MINIMUM OF TRAUMATISM.\*

OTTO T. FREER, M.D.

CHICAGO.

It is not my purpose to describe a new operation for the correction of deflections of the nasal septum, but to give my experience with the methods that I prefer and to mention the additions to their technique and instrumentarium suggested to me by their use. These methods will also be contrasted with the type of another class of operations that has become popular with many, to the exclusion of other procedures. I refer to the straightening of deflections in the way described by M. J. Asch.

While the means advocated in this paper inflict a minimum of traumatism on the nasal interior, the operation of Asch is accompanied by an amount of force and injury out of all proportion to the resistance of the frail partition that is to be straightened. Asch's procedure is intended to accomplish by force under narcosis, in a few minutes, without the aid of sight, a result which can be attained only by the use of much more time and with the infliction of some pain by rhinoscopic methods. With these, however, the end is gained with the neatness, deftness, exactness and adaptability to varying conditions only possible when an operation is done with the help of vision, while in operations of the Asch type, no consideration can be taken of the endless variety in shape and extent of septal deflections.

In addition to the large proportion of quite atypical deformities, those that I have seen group themselves mainly into two general types of angular and bowed deflections. The angular variety is more apt to be limited in my experience to the cartilaginous septum than the bowed. Often the angle is far forward so that the deflection may be seen by lifting the ala of the nostril. Very frequently it involves the osteo-cartilaginous junction, so that the receding posterior plane of the angle is more or less bony. While the anterior surface of the angle is apt to jut out abruptly, the posterior or hidden surface generally slopes gently back towards the naso-

pharynx so that it forms the longer limb of the angle and causes a general narrowing of the nasal passage along the bony part of the septum, and even where the angular deformity is wholly within the cartilaginous septum I usually find that the bony portion behind it bends into the narrowed naris, slightly, but enough to obstruct breathing noticeably. The ridge at the summit of the angle, or corner of the angular deflection, usually has a vertical direction or extends upward and backward in the direction of the upper border of the vomer.

The curved or bowed deflection is quite common and often extreme, so that its anterior portion may be visible without a reflector, protruding like a red tumor into the nostril. The bowed deflection, as I have seen it, almost invariably involves the bony septum, often for nearly its entire extent. With both angular and bowed deflections, but especially the latter, the anterior lower angle of the quadrangular cartilage is often found dislocated from the superior maxillary crest and seen to project across the nostril containing the septal concavity. The concavity of both angular and bowed deflections presents a certain uniformity of shape not possessed by the convexity, which is often varied by spurs, crests and thickenings. The concavity in both varieties usually appears as a deep pocket whose convex walls unite at the bottom at an angle, often acute, lying opposite the point of greatest convexity. The bowed deflections are more apt to be thin-walled than the angular ones, and the latter are more prone to be associated with crests and thickenings. Often, however, what appears to be a solid spur or crest proves on measurement to be a hollow prominence. Some deflections are so exceedingly thin that the cartilage is of the thickness of an egg-shell. The cartilaginous septum, as I have measured it, is commonly one-eighth to three-sixteenths of an inch in thickness; the cartilage without the mucosa in most cases is from one-sixteenth to one-eighth of an inch thick, but may attain a thickness of five-sixteenths of an inch in some cases.

From the foregoing it is evident that septal deflections vary so greatly in shape, thickness and extent that operations for their correction can not well be of an unvarying, typical kind as is the Asch procedure. The operator who would accomplish his end with the least injury must be ingenious, make a different plan of operation for almost every case and find new ways for overcoming unexpected difficulties as he goes on. It is especially the bony septum that presents these difficulties and Mackenzie's statistics show how often this part of the septum is involved in the deflection; in fact a very moderate experience will demonstrate it to any one. Asch's operation, as admitted by those who practice it, is not well fitted to cope with bony deflections. It is a procedure largely depending for its results on the use of blunt force, producing fractures and contusions, and it is my experience that the use of blunt force in the nasal interior, as elsewhere in the body, creates far more reaction, devitalizes the tissues more and invites infection more than does the use of cutting methods. I advocate, therefore, as far as possible, resection of the redundant cartilaginous septum in preference to forcing it to assume a straight line by means of infractions after incisions. Resection is much more an operation of precision than fracture. The latter will not always occur where it is desired, will extend too far or occur in the wrong place, and involves the temptation to use violence to overcome the resiliency of the septum.

To E. F. Ingals belongs the credit of having origin-

\* Read at the meeting of the Chicago Laryngological and Otolaryngological Society, Jan. 21, 1902.

ated in 1882 the type of operation designed to correct the septal deformity by complete removal of a portion of the quadrangular cartilage, the so-called resection of the septum, or window resection, as it is named by Krieg. Four years later Krieg reported his "Fensterresektion," which differed from that of Ingals in the manner of the incision in the mucous membrane and in that he removed the entire deflected cartilage and not merely a triangular portion in front. Boenninghaus followed with an admirable article in which he laid stress upon continuing the resection into the vomer and perpendicular plate if necessary, taking away not merely the bent cartilage but the deflected bone as well. Without knowledge of Krieg's or Boenninghaus' operations I began in May, 1901, to remove by resection completely, in such cases as seemed suitable, the cartilaginous portion of the deflection as far as it extended or until the bone was reached. Consultation of the literature on the subject has shown me that my method is not original but that Krieg had continued the Ingals operation backward long before I had thought of doing so. Neither

Bowed deflection of the septum seen from in front. The tip of the nose is raised by the thumb of the operator. 1. Convexity of deflection in left naris. 2. Dislocated anterior inferior angle of the quadrangular cartilage lying across the entrance to the right nostril. 3. Cutaneous septum.

he nor Boenninghaus give Ingals the credit that is due him, probably from lack of attention to American literature on the subject. Among my own cases I have found, so far, 15 suitable for the resection operation, and have corrected the deflections by this method. Krieg reports 130, Boenninghaus 19 cases.

It naturally suggests itself that the extensive removal of cartilage or bone from between the mucous layers of the septum will deprive the external nose of support and that it will sink in. This would be the case if the nasal septum were a supporting wall for the external nose instead of a mere division between the nares. The intrinsic cartilages of the external nose, the nasal bones and the anterior edge of the quadrangular cartilage maintain the form of the nose even if the rest of the septum be gone. Cases are constantly presenting themselves where loss of all of the quadrangular cartilage and often of large parts of the bony septum as well, as the result of disease, is not accompanied by deformity

of the external nose. Where this sinks in, it is because cicatricial retraction draws the facial nose back into the nasal interior. The only influence on the shape of the external nose that I have seen result from removal of the deflected cartilage is bringing the nose into the median line when it is twisted to one or the other side, an effect very agreeable to the patient. I have never seen tilting upward of the tip of the nose or sinking in of its bridge. As an example of the fact that this does not need the support of the septal cartilage I refer to the custom of most operators to excise the anterior lower portion of the quadrangular cartilage when this is dislocated from the superior maxillary crest. It is quite evident in these cases that the cartilaginous external nose derives no support from the septum and no surgeon fears injury to the nasal profile. Neither

Septal deflection seen from right nostril, showing concavity of the deflection. 1. Angular pocket at bottom of concavity of deflection. 2. Inferior turbinate body. 3. Nasal speculum.

Boenninghaus nor Krieg speak of any such consequence to their numerous operations in which they cut away all of the cartilage or bone involved in the deflection, and Boenninghaus denies the possibility of deformity. Boenninghaus reports several cases in which he removed the entire quadrangular cartilage and in some cases extensive portions of the vomer and perpendicular plate as well.

While the supporting function of the septum may be therefore disregarded, its physiologically important mucosa must be respected and perforations are to be avoided if possible. Boenninghaus says that the mucosa will regenerate in time a new cartilaginous and bony septum from the perichondrium and periosteum which

it contains. In two of my cases examined three months after operation, I found partial reformation of cartilage in one and no attempt at its replacements in the other.

I do not continue my resection into the bony wall as do Krieg and Boenninghaus, who cut away large portions of the vomer or perpendicular plate if deflected, but prefer to fracture the bony septum with Roe's forceps after preliminary chiseling or trephining. This previous weakening of the bony septum in the directions desired limits the force required for the fracture to the least degree and indicates its direction.

The methods of operation to be described are designed for the typical deflections mentioned, as it would be impossible to detail the variations made necessary by divergences from the usual types.

For the local anesthesia I employ powdered cocain. This I apply with a small, moist swab to both sides of the region of the septum to be operated on. It produces an intense insensibility, but so limited in area that

Right nostril showing angular deflection with mucous flap reflected forward. The triangle of cartilage has been outlined with the cartilage knife, and is being raised at its anterior border with Ingals' spud, which is lifting off the mucous membrane in the opposite nostril. The dotted line indicates cut through cartilage. The arrow shows direction of cut along base of triangle underneath bottom of deflection and therefore for the most part invisible. 1. Triangle of cartilage. 2. Ingals' spud. 3. Reflected flap of mucosa.

I have never seen cocain intoxication, as the amount of the drug used is small. An advantage of cocain in the dry state is that it contains none of the poisonous products of decomposition of the drug liable to occur in solutions. In the nasal vestibule, where the septum is covered with pavement epithelium, the sensitiveness is not entirely removed by cocain, as absorption is deficient, but back of this region the anesthesia is so complete that even children permit excision of large portions of the cartilage without complaint. The bony portions of the septum, however, remain much more sensitive, so that chiseling, trephining and fracturing cause a good deal of pain at times, but nothing that may not be endured with moderate fortitude, and no more than is inflicted in sawing away an exostosis. As long as the operation is confined to the cartilage the chief annoyance felt by the patient is due to holding the nostril open with the speculum, so that his patience is taxed rather than his courage in enduring pain.

Adrenalin applied in the strength of 1 to 1000 will often, especially in young subjects, make the operation practically bloodless and so shorten it greatly, as the blood does not interfere with vision in the usual manner. In other cases adrenalin has no appreciable effect on the bleeding. A fresh application of cocain has, however, never failed in my experience to act as a prompt but temporary hemostatic, so that I employ it to permit progress of the operation when the bleeding is great enough to interfere with a view of the field.

Before operating, the usual precautions as to asepsis are employed and a large number of swabs are placed on applicators to be used to wipe away blood, as even a drop of this will interfere with a view of the narrow cavity in which the work is done.

Taking, for example, an angular deflection far forward, an incision is made down the crest of the angle and forward at its base so as to outline a triangular flap of mucosa. This incision is made with a small knife whose blade is bent on the flat on the shank at an obtuse angle. The blade is one-half of an inch long and three-sixteenths of an inch wide. The triangular flap of mucosa thus outlined is pushed away from the cartilage in the usual manner with Ingals' nasal spud. The exposed triangle of cartilage is cut around at its borders with the small Ingals cartilage knife designed to cut merely through the cartilage without injuring the mucosa of the opposite side. The triangle of cartilage, after separation at its margins, is freed from the mucous membrane of the neighboring nostril with a spud. This is accomplished by passing the spud through the incision in the cartilage at the anterior border of the isolated triangle of cartilage, which is seized with rat-tooth forceps and finally removed. When the angular deflection extends far up towards the nasal roof it is often difficult to sever the attachment of the triangle at its uppermost part. To meet this difficulty and for continuance of the operation further back after the triangle has been removed I have designed two modifications of Ingals' cartilage knife, a right and a left hand knife, for cutting up or down. In these knives the plane of the flat surface of the little blade is at right angles to its slender shank and may therefore be used far back or high up in the nasal cavity. Its blade is only one-eighth of an inch long and if the cartilage be thicker than this it may be made to sever it by pressing the knife into its substance while making repeated cuts. In all but very rare cases it will sever the cartilage at the first incision. I have never made perforations with these knives and do not find it necessary to keep the finger in the opposite naris to feel if the blade be cutting through as Boenninghaus recommends for his incisions, but find this proceeding of value to support the septal cartilage so that the knife can enter it.

Up to the removal of the triangle of cartilage the operation has been a typical Ingals one. Its continuance, as far as the cartilage is concerned, is practically the method of Krieg. The removal of the triangle of cartilage leaves exposed to view the inner surface of the mucosa of the opposite side of the septum. At the posterior border of this raw area the cut edge of the septal cartilage presents as a snow-white vertical narrow surface. The spud or a slender spatula is inserted between the outer edge of this surface and the mucosa of the convex side which is separated from the cartilage as far back as it can be reached. While the cutis-like mucous membrane of the anterior one-quarter of the cartilaginous septum is difficult to undermine with the

spud and has to be dissected away from its attachment, the mucosa of the parts of the septum back of this may be peeled from the underlying bone or cartilage with perfect ease. It is thin and delicate and not easy to see. The mucous membrane of the opposite or concave side of the deflection is next separated in a similar way, great care being taken not to perforate it. When this step is completed the cartilage or cartilage and bone of the posterior limb of the angle of deflection is bare of mucous membrane on both sides as far back as can be reached and if it be moderate in length, in its entirety. The next step is removal of the bared cartilage. For this purpose the little cartilage knives with right-angled attachment of blades mentioned are used. According as the right or left nostril is the field of operation one or the other is introduced between the mucosa of the opposite naris and the septal cartilage and pushed back as far back as the mucous membrane has been separated from its base. The point is then turned outward and made to pierce the cartilage. Next the blade is swept around the base of the cartilaginous flap to be removed, cutting it through. Usually the cartilage knife will catch the loose piece like a hook and bring it away. If this does not occur the fragment may be twisted off from its remaining adherence with forceps. Another white narrow surface, the edge of the cut cartilage, will now be in view and if the deflection be not entirely removed more of the mucosa should be peeled from both sides of it farther back, in the manner described, and another piece of cartilage be removed. Though the work gets more difficult the further back progress is made, it is nevertheless not a hard matter to dissect out the cartilage from between the mucous layers as far back as the bony septum. If the deflection has been entirely taken out in the manner described the operation is ended and the nose ready for tamponing, but if the posterior surface of the deflection extend back into the bone I begin the use of chisels as a preparation for the Roe forceps. Doubtless, in some cases the method of Krieg and Boenninghaus of removal of the bone by fragments with cutting forceps is preferable, but in my cases I have usually found it so difficult to work at this great depth within the naris that other and less tedious methods seemed preferable. The chisels I use are those employed by dentists for the cutting of enamel; any narrow-bladed one will do. The chisel is applied to the white edge of the cartilaginous strip remaining in front of the bony part of the deflection and pushed back within the cartilage until it rests firmly on the anterior edge of the bone, which is usually the vomer. It is then driven longitudinally into the bone as far back as needed. The bony septum is thus easily fissured in such directions as seems desirable. It is a matter of no consequence if the chisel pierce the mucosa of the opposite side, as slits in the septum back of the denuded area of mucous membrane of the opposite nostril do not cause permanent perforations. It is easy, however, to keep the blade of the chisel from going through in most cases. When chiseling is complete I apply the largest blade of the Roe forceps that will enter the naris and fracture the bony deflection in the manner described by Roe. The use of this instrument without preliminary fissuring or trephining I have not found satisfactory. I have never succeeded in correcting cartilaginous deflections with it and have found that as soon as the forceps was removed the cartilage sprang back into its old place. For bony deflections, however, after preliminary weakening as mentioned it is in most cases an entirely satisfactory instrument. It has been my experience that

some elastic septa in young subjects can not be made to break sufficiently with Roe's forceps to become straight, or that they are too resilient to break at all when it is used. In these cases the resection may be carried as far back as possible and I have found Ingals' nasal punch forceps, which makes several parallel slits through the septum, a useful instrument to destroy the resiliency. Where the bony septum is thick and massive, as it is very apt to be at the base instead of merely weakening it with the chisel a part of its substance may be removed with this instrument or with the trephine, several cores being taken out after the manner of Ingals. Where the septum is thin and elastic it is hard to apply the trephine so that it will follow the bone as the anterior edge of this is so movable in these cases

Later stage of operation upon deflection shown in Fig. 3. The triangle of cartilage has been removed and shows the cut edge of the septal cartilage. 1. Hollow of deflection exposed by peeling away of the mucous membrane of the opposite nostril. 2. Freer's angular cartilage knife making downward incision at posterior part of bared deflection. 3. that it slips away as soon as the trephine begins to rotate. In the majority of cases perfect success may be attained with the chisel and Roe's forceps.

Sometimes a crest or spur in the opposite nostril makes the application of this instrument impossible or unsatisfactory. The sawing, chiseling or trephining away of these obstructions, in addition to the procedures mentioned, is a matter of course and should be done at the same time.

The operation is not complete until the patient can breathe perfectly through the previously obstructed nostril without the use of pressure to force the septum to-

wards the opposite naris. No tubes are needed to maintain the correction as, under the conditions established, the deformity can not recur, because the cartilaginous deflection has either been removed bodily or what little remains of it at the posterior part is held in proper position by the inflected bony portion of the septum, which shows no tendency to spring back into its old position after being broken. The after-treatment consists in packing the naris after the manner of Ingals with a long strip of lint. This it is my custom to impregnate with powdered bismuth subnitrate, as I have found that a tampon filled with this antiseptic will remain odorless and fresh for as long as ten days in the nasal cavity. Whether it would stay so longer I have not tested, but have not so far found a bismuth tampon putrid when removed. The object of tamponing is to avoid secondary hemorrhage and to make the flaps of mucous membrane apply themselves so that they will heal by primary union. Krieg and Boenninghaus remove the reflected mucosa of the convex side, claiming that it forms hyper-

Still later stage of operation. The deflection has been removed all but its posterior portion which is partly cartilaginous and partly bony. The inferior turbinated body has been exposed to view by removal of deflection. 1. Remains of deflection. 2. Reflected anterior flap of mucosa. 3. Inferior turbinated body. 4. Mucous membrane of opposite nostril. 5. Separated mucous membrane of convex side of deflection, lying loose in naris.

trophic prominences later. This has not been my experience if primary union can be obtained and this results almost invariably, shortening considerably the time of healing. Previously to introducing the lint strip the flaps are neatly applied and protected from displacement during the tamponing by placing against the wound surface one of Ingals' metal guards. The tampon is removed on the fourth or fifth day and not replaced. To avoid crusting during healing, the patient is directed to insert daily into his nostril a 2 per cent. ointment of salicylic acid in lanolin and vaselin equal parts. A spray of normal salt solution is also employed by him.

The patients are not directed to go to bed but usually go about their business in from one to three days. They do not need iced sprays or cold applications to the ex-

ternal nose as after the Asch operation. They do not have to endure the annoyance of a tube for weeks. The operation is not as Emil Mayer says of the Asch, "an operation of magnitude" as far as the traumatism is concerned. I can recall no case in which septic symptoms or suppuration followed it.

Perforations of small size are not always avoidable and are generally about one-quarter of an inch in diameter. Boenninghaus states that he has not seen the irritation and crusting supposed to be due to them. Neither have I found these conditions after healing is complete though the perforation may have occurred far forward. A mere slit in the mucosa of the opposite nostril after the cartilage has been removed will give rise to a perforation, as during healing its borders retract, but a perforation of this kind will have normal mucous membrane to line its edges; hence it will not crust, while a perforation in the cartilage will have a rim of this substance from which the mucosa has shrunk away, and which will therefore be covered by cicatricial tissue not possessing the normal epithelial surface and hence liable to give lodgment to scabs. This, I think, accounts for the absence of crusts when the perforation has been made through mucous membrane from which the cartilage has been detached. During the first two to eight weeks after the operation, until the epithelial surface has become normal again, there is always a tendency to drying of secretions in the nostril which has been operated on.

The time required to complete the operation described is from one-half to two hours, seldom longer, than one hour. The reason for its lengthiness is the accuracy of vision required. A drop of blood may obscure the minute field of operation so that much time is used in swabbing the wound dry. Since the introduction of adrenalin, in the majority of cases the proceeding is practically bloodless and hence much more speedy.

Chloroform may be used for the employment of the Roe forceps but only in one case have I found it needed. The anesthesia must be complete, as in half narcosis the patient struggles against the introduction of the instrument.

When children are old enough to sit still during the operation it may be performed upon them as well as upon adults, as the resection is generally unusually easy in their case because the mucosa separates with great readiness from the cartilage, and this extends further back into the naris before bone is reached. It is not well, however, to attempt the operation unless the child has passed his tenth year, as before this time his patience can not be relied upon.

Fainting during the operation has rarely occurred in my practice and then only in the beginning of the procedure. No patient has actually swooned but some have felt so giddy and weak that they had to lie down for a time before the operation could be proceeded with. Faintness seemed to me to be due more to fear than any other cause, for when the patient had recovered from his weakness and the resection was well under way, this class of patients endured it as well as any and the fainting fit was rarely repeated. If the tendency to syncope in these cases were due to cocaine intoxication it would not be so readily recovered from and would be repeated after each renewed application of the drug. This does not occur.

The hemorrhage, even without the use of adrenalin, is usually confined to the soaking of about ten to twenty cotton swabs with blood. When the correction involves

the bony part of the septum the bleeding is greater than when it is confined to the cartilage, but is never a noteworthy feature. Nevertheless, a tampon should always be inserted at the end of the operation as secondary hemorrhage may supervene some hours after its completion and it seems to me that the use of adrenalin predisposes to this complication.

Sloughing of the exposed mucous membrane of the opposite naris has never occurred in my experience. Pain after the removal of cartilaginous deviations is insignificant, but infractions of the bone create some painful reaction for a day or two, though never enough to make morphin necessary.

One of Freer's angular cartilage knives. 1. Blade of knife attached to shank at angle on the flat. 2. Cutting edge of blade.

The breathing through the nostril that has been operated on is freer immediately after the operation than for some weeks afterward, as congestion and swelling of the mucosa of the opened naris and a certain amount of provisional callus growing on wounded bone and cartilage need time to be absorbed. After two months or more the nostril becomes as open as right after the operation.

In contrast to the method described, the operation of Asch represents a departure from the more skilful procedures of rhinology and a return to those of the general surgeon not having special practice in visual operations within the nasal cavity. I have referred to Asch's

familiar. The mode of infection in this case is obscure, but it seems possible that as a result of fracture, a fissure in the perpendicular plate entered the septum of the sinuses and caused a double infection. These remote parts of the nose would be quite out of danger of injury from the localized fracture produced by the Roe forceps.

The severity of the traumatism induced by the Asch method is emphasized by the need of keeping the patient in bed for three days and the iced sprays and cold applications used in the after-treatment.

That the Asch operation is designed especially for operations on the cartilaginous septum is admitted by

even those who employ it and a consideration of the instruments and mode of procedure will show that it is not adapted to deal with bony deflections, not to speak of complicating exostoses and cecchondroses. Yet no one can tell with certainty until the anterior part of a septal obstruction is removed from the naris what second and more formidable obstacle may be found behind it.

When the surgeon in doing an Asch operation finds that after removal of the cartilaginous deformity he has a bony part of the deflection to correct he will certainly be tempted to forcibly straighten this, impelled by a desire to relieve his patient in one operation. The Asch forceps, with its flat and parallel blades is not at all

Ingals' submucous cartilage knife. (One-half size.)

Freer's flat angular knife for incision of mucous membrane of the nasal septum. (One-half size.)

operation as one involving the use of force. As examples of the results of this I refer to two cases reported by Stucky. Both of these had been operated upon by experienced operators in the manner of Asch. In the first case the operation caused a fracture of the lower turbinal closing the lower meatus and a fracture of the middle turbinal forcing this against the septum. Almost entire removal of the lower turbinal and turbinectomy of the middle were needed to restore the patient's health. Much granulation tissue had to be everted from the lower meatus. In the second case two weeks after the operation the lower and middle turbinal showed plainly the defects of traumatism. That the

suited to this work. To quote Roe: "With flat-bladed forceps it is only possible, except by twisting the blades to bring the bend in the septum up to the median line, which seldom suffices to fracture the bone, and then only when the bend in it is so great and the blade of the forceps sufficiently wide to bring a large amount of force to bear at the center of the angle."

It seems to me that the only way that the Asch forceps can be made efficient is by twisting the septum with it, a proceeding rightly forbidden by Asch and Mayer as dangerous. To complete the Asch operation with the Roe forceps where there is bony deviation would be a better proceeding, but their action is unreliable unless

Chisel for bony septum.

results of the Asch operation may be even more serious is shown by the case reported by Robert Levy in which fatal sepsis with thrombus of the posterior cerebral artery and endocarditis and pericarditis followed an Asch operation. Though Emil Mayer in commenting on this case states that sepsis may follow almost any rhinological operation, the danger of this complication is certainly greatly increased by forcible manipulations within the nose such as characterize the Asch method. A case has come to my notice in which suppuration of both sphenoidal sinuses was a sequel to an Asch operation. The surgeon was one of extraordinary experience and skill and one to whom the procedure was thoroughly

the septum has been previously weakened by chiseling or trephining and this can not be done with accuracy without the aid of vision. I do not see how an exostosis behind a cartilaginous deflection can be distinguished from a bony deflection during an operation done without the aid of sight; yet to attempt to crush in an exostosis with fracturing forceps is obviously useless and liable to do injury. It seems to be impossible to accurately determine the extent and nature of a bony obstruction during an Asch operation. Max Thorner speaks of additional operations on spurs and posterior obstructions after the septum is healed in the new position. The bony deformity may be corrected after this

manner, but this means two operations to the patient, the first of which was out of all proportion in gravity to the result obtained, which may be so easily reached by resection as described.

The method I have described permits removal of bony obstructions at the same time that the deflection is corrected. There is one condition which may be saved for a secondary operation with profit and this is the dissection from its bed of the anterior lower angle of the quadrangular cartilage when this is dislocated from the superior maxillary crest and lies across the entrance to the nostril of the concave side of the deflection. The

Ingals' spud. (One-half size.)

reason for postponing the removal of this angle is the fact that it is most readily dissected out by means of an incision in the nostril of the concavity and it is not desirable to wound both nares at the same time.

There is a good deal of hemorrhage during the Asch operation. This is admitted in the descriptions of most operators. Stucky graphically speaks of "the patient under an anesthetic bleeding profusely and choking with blood."

The Asch and Mayer tubes are objectionable. An operation for the correction of septal deflection should be so perfect that the nostril remains open without support. The tube is an irritating foreign body like any

Ingals' nasal spatula. (One-half size.) Sets of three varying in width, angle of 45 degrees. Made of steel.

other within the nose and in one that has just been wounded by an operation is doubly irritating. It is not to be compared in harmlessness with soft lint, made slippery with imbibed mucus. Max Thorner, an ardent advocate of the Asch operation, says: "There is no doubt that granulation tissue will spring up around, above and below the tube." Richardson, who warmly endorses the Asch method, says: "Nor can the fact be denied that such a body as a splint of hard rubber placed within the nasal cavity will produce temperature and inflammatory reaction." He speaks of "exuberant growth of granulation tissue" about the edges of such a foreign body.

Roe's septum forceps.

The position of the head in the Asch operation produces venous congestion and increases the bleeding during its performance, while the upright position assumed by the patient during a rhinoscopic operation together with the effect of cocaine limit the bleeding to a minimum.

General narcosis includes the usual dangers and disagreeable after-effects and a rhinoscopic operation can not well be done where it is employed. Vision is difficult with the patient lying down and the tendency to hemorrhage soon makes a view of the field of operation

impossible. E. F. Ingals in a personal communication has informed me that the correction of septal deflections in children with the use of anesthesia has proven unsatisfactory to him for the reasons mentioned. The introduction of a blunt separator into the naris at the beginning of the Asch operation to discover and break up adhesions seems to me a crude and rough way of finding what can be discovered with a probe without difficulty and irritation by means of rhinoscopy. Adhesions between the turbinates and septum are very rare and where they exist are best severed by cutting instruments.

There is no reason for tearing them apart with blunt ones. It seems to me that the chief reason for the growing popularity of the Asch operation is its ease of performance and the time saved by the fact that but a few minutes are required for it. Its chief defects are that it can not deal intelligently with the frequent bony obstructions and that it does not remove the redundancy of the septum. Though it must be admitted that the procedure I have advocated is at times tedious and requires great painstaking; as elsewhere, time and care give better results than hasty and forcible work.

#### THE INDICATIONS FOR MYOMECTOMY IN YOUNG MARRIED WOMEN, WITH A REPORT OF FOUR CASES OF STRANGULATION OF FIBROIDS DURING PUERPERAL INVOLUTION.

EDWARD REYNOLDS, M.D.

BOSTON, MASS.

My belief that the comparative rareness of the accident which forms the subject of this paper, together with the absence of any description of it from the more accessible literature, makes me think these four cases worthy of record; and, moreover, that their considerable clinical importance makes a systematic presentation of the accident worth attempting. These are the two objects of the present paper.

CASE 1.—M. L., a primipara of 30, seen March 12, 1898, with Dr. C. W. Townsend. She was delivered by normal labor on March 9. At the time of the labor, Dr. Townsend discovered a fibroid tumor as large as a mandarin orange on the anterior face of the uterus, near the left cornu. On March 11, she began to have extremely sharp pain in the region of the fibroid, which then became very tender to the touch. This pain came in paroxysms, was intermittent, and evidently very severe; relieved only after four 1/8 gr. doses of morphia subcutaneously. The next morning the patient was free from pain and the fibroid was not tender. At noon the same pain recurred; for a time it quieted down, and then came on in the afternoon as severely as before, still intermittent, but in the height of the paroxysms almost continuous. I saw her at this time.

The fibroid was easily recognized, and was exquisitely tender to the touch; the abdomen was swollen and tympanitic, the rectum empty and inflated, and both rectum and vaginal vault were hard and board-like in feeling and apparently drawn up into the pelvis. The diagnosis of strangulated fibroid seemed clear, and I was inclined to think that there was a little pelvic peritonitis present. As the pain became less during the time I was there, I advised no treatment, but close watching; the pain gradually ceased and did not return; the patient made a good recovery. The fibroid rapidly diminished in size, and Dr. Townsend tells me it could not be felt six weeks later. At a second confinement on Nov. 8, 1899, two small fibroids, each the size of half an English walnut, were to be felt on the uterus at the same spot. The patient made an absolutely normal convalescence from this second labor.

CASE 2.—I saw this case with Dr. G. K. Sabine and Dr. S. A.

Houghton, of Brookline, on Dec. 22, 1898. She was a multipara, 38 years old. All her labors had been easy and successful. She had a spontaneous miscarriage, eight years ago, and was told by her physician that she perhaps had a fibroid, but no definite diagnosis was made. She has been in the best of health since. She was delivered Dec. 1, 1898, and made a normal convalescence, unmarked by any symptom or elevation of temperature, until December 19 (18 days), when she felt some pain of neuralgic character on the outside of the left thigh, and had a moderate elevation of temperature (see chart). The next day there was some paroxysmal abdominal pain and the temperature rose higher. The uterus was found by Dr. Sabine to be at the level of the umbilicus, but not tender. The abdominal pain was extremely severe, and only partially relieved by large doses of morphia. There was great tenderness to the left of the uterus and some tympanites, flatus passing freely. On the next morning, the fourth day of the attack, the distension was more marked; the pain was now continuous, but still marked by occasional paroxysmal increase. There was now extensive tenderness over the uterus, and also over a large mass, which was now felt for the first time, to the left and on a level with the fundus, apparently continuous with the uterus. The sharp neuralgic pain in the outside of the left thigh had continued

CASE 2.

throughout this time, and was now very distressing. I saw her at 5 p. m. of that day, and my notes say: "Aspect slightly peritoneal. Pulse a little wiry. Temperature 103. Coils of intestine perceptible to the touch and perhaps to the eye in the upper abdomen. On vaginal examination a mass to the left apparently continuous with the cervix. Diagnosis thought to lie between a strangulated fibroid and a collection of pus. Some peritonitis is present in either case." We decided to wait until morning before operating in the hope of improvement or more definite indication. On the next day, December 23, at 9 a. m., the condition was as follows: "Facies worse. Coils of intestine distinctly visible to eye in upper abdomen. Face flushed, finger nails cyanotic, color in them returning slowly after pressure." The patient's general condition was so bad that I thought that the shock of an abdominal operation would be almost certainly fatal, and advised an immediate vaginal incision, on the ground that bad as her condition was, it was probably shortly to become hopeless.

Under ether the uterus was found at the umbilicus, and a mass was felt to its left of about equal size and continuous with it. The lower end of the mass was at about the level of

the internal os, small, tapering and firm. A finger forced through the cervix found the uterine cavity unaltered in shape and at least four inches deep. An incision was made through the mucous and submucous tissues to the left of the cervix, the finger was forced up through the connective tissue into contact with the lower end of the mass, which was then felt to be evidently a fibroid. A pair of sharp scissors was plunged deeply into the tumor, opened and withdrawn. A finger pushed into this opening found the tissues extremely friable, and enlarged the opening in the tumor freely, extending it to the full length of the finger. The withdrawal of the finger was followed by a smart flow of rather thinnish blood. This was allowed to continue for about two minutes, but as at the end of this time it was rather profuse and continued without diminution, the hole was then plugged with iodoform gauze. The patient came out of ether rapidly, with the pulse rather better than before operation. During the evening and night the patient slightly improved, the temperature falling. The sharp pain in the left thigh continued, but was now relieved by morphia and the patient passed a fair night. The next morning she looked decidedly better and was complaining of nothing except of intense pain in the left thigh. The gauze was withdrawn and this pain instantly and finally ceased. From this time on there was a considerable, though decreasing flow of serum from the wound, and the patient steadily convalesced, there being no new symptoms. As this patient's age makes another pregnancy unlikely, and the fibroid has caused no symptoms, it has been left undisturbed.

CASE 3.—Mrs. C. W. was seen on Feb. 3, 1900, with Dr. Wilard H. Pierce, and Dr. G. B. Twitchell of Greenfield, Mass. She was a primipara, 26 years old, 7 years married, and has always desired children, but has never been pregnant. She has always been anemic, but was otherwise well, except three years ago, when she had an acute abdominal attack of unknown cause and gradual onset, which kept her in bed for three weeks and under treatment for three months, and was considered at the time a salpingitis, though as the appendages of both sides were found normal at the time of operation this was probably a mistaken diagnosis. She made an entire recovery, has been very well and free from pelvic pain ever since. She was delivered Feb. 1, 1900, by Dr. Pierce, by difficult high forceps following an atonic labor, of a still-born child. On February 2, she was attacked by tenesmic pains in the rectum, appearing at intervals, with comfort between, and at first relieved by morphia, but during the night they became so severe that morphia did not relieve them, even though a total of one grain was given subcutaneously (the patient had no habit). They finally disappeared after primary anesthesia by chloroform, but only to reappear in still more severe form a few hours later. I saw her about noon (two days and a half after delivery); the temperature was then 104.4, the color and appearance very bad, the nails cyanotic, the abdomen tympanitic, the coils of intestines outlined to the eye under the abdominal wall. Tenderness was so extreme that the patient was unwilling to have the abdomen touched without ether, and pain was again severe. Under ether I found the uterus retroflexed, and consequently crowded against the rectum, and on raising it found a fibroid the size of an orange in the posterior wall and slightly to the left. The patient recovered from ether free of pain.

As the tumor was plainly too high for a vaginal incision and I anticipated considerable relief from raising the retroflexion, and as anesthesia had each time relieved the pain, I recommended that an expectant policy should be pursued for the immediate future; that the patient be anesthetized, and the uterus, if necessary, raised as soon as an attack of pain began. If the attacks were persistent and the condition grew worse, I proposed to make an incision into the tumor from within the uterus, for the purpose of drainage. There were fortunately no further attacks of paroxysmal pain, but the temperature continued high, abdominal tenderness and moderate pain persisted, tympanites was for some days troublesome, and the outcome of the case at first looked uncertain; but this condition passed off, the patient gained rapidly, and the remainder of

the convalescence was normal. I regret that, owing to the illness of her physician, I was unable to obtain detailed records of this portion of the case.

On August 14 she came to my office, anemic, but otherwise well and free from symptoms. She was exceedingly anxious to have the fibroid removed, in hope of another pregnancy, and from fear of a repetition of the trouble. On examination I could find nothing but a markedly tender spot at about the site where the tumor was last felt, and advised the use of glycerin depletion till the heat of the summer was over. During the next two months she had two slight attacks of acute abdominal pain, accompanied by some obstruction of the bowels. On September 17, I opened the abdomen; I found the intestines and omentum adherent together in a large mass on the left side, the omentum in front, and the sigmoid behind the left broad ligament and appendages. These adhesions were thoroughly separated, though with much difficulty, being exceedingly tough and well organized. There was a fibroid the size of a very small English walnut on the posterior surface of the uterus near the fundus. It was exceedingly adherent to its capsule, and it was a long and tedious process to take it out from its bed. The tube and ovary were normal and were not removed.

There was almost uncontrollable pain referred to the left lower abdomen for the next twenty-four hours, although there was no vomiting, the bowels moved spontaneously twice in the first twenty-four hours, and gas passed within a few hours of the operation. This pain was finally and definitely relieved after taking large quantities of hot water by the mouth. A considerable quantity of feces was passed in the first two or three days after operation, although four days had been devoted to care of the bowels before it, and it was supposed that they were thoroughly unloaded. The downward movement of this mass of feces was probably the cause of the pain above referred to. The remainder of the convalescence was uneventful and the patient is in good condition to-day.

CASE 4.—Mrs. A. L., seen Dec. 21, 1900, with Dr. A. C. Aldrich, of Somerville. The patient was a iv-para, 30 years old. She was delivered on the morning of December 18, by a normal easy labor. Was comfortable and normal till the evening of the next day, when she was attacked by intermittent pain resembling labor pains but referred to the left ovarian region, and vomited at short intervals all night; the temperature being 101 at 1 a. m., and the pain increasing until she was given a fourth of a grain of morphia subcutaneously at 4 a. m. This was followed by relief, but the pains recurred in the afternoon of the following day; the temperature rose then to 105, the pulse to 110. The abdomen was then slightly tympanitic, and not very tender, except in the left ovarian region; the pains more moderate than on the preceding day. On the 21st, when I saw her, the temperature had been 101.8 all day, the pains were moderate, the pulse about 80. On examination the fundus of the uterus was about at the umbilicus, and anteverted. On the left cornu there was a moderate projection, like a small fibroid. This was exceedingly sensitive to pressure, but there was no tenderness anywhere else. She was recommended ether for the relief of pain, and to abstain from nursing, since it had been noticed in this case that putting the child to the breast produced an increase of the pain. The trouble gradually passed away and no ill effects persisted, yet it must be noticed that the elevation of temperature and the abdominal pain and tenderness presented a very alarming picture at the time, and until the diagnosis had been established. Mrs. L. gave the history of having had a similar attack after the birth of her first child, but had escaped it after the second and third deliveries.

The clinical picture presented by these cases seems to me an exceedingly clear one. In each case the patient is attacked within the first few (2, 18, 1, and 1 respectively) days after labor, by severe intermittent paroxysmal pain bearing a close resemblance to labor pains, but more severely painful; the pains being referred in each case to the spot at which on subsequent

examination a fibroid is found. A few hours of this pain is followed by considerable pyrexia, tympanites, vomiting, abdominal tenderness, and, in short, all the symptoms of a pelvic peritonitis.

The detection of the tumor varies in ease with its situation. In the first case, in which it was fairly large and on the anterior wall of the uterus, it was found with the greatest ease. In the second case it was not observed at all until the patient was in a very bad condition, by which time it is probable that it had greatly increased in size from the edema consequent on strangulation, but even then its characteristics were not easily made out until after ether had been given. In the third case it was impossible to detect it without ether though it was then plain. In the fourth the diagnosis was made more from symptomatology than from the examination, although on careful examination a localized irregularity of the contour of the uterus, probably representing a very small fibroid, could be made out with fair certainty. This case was promptly relieved by morphia and was throughout of less severity than any of the others.

The features of an intermittent paroxysmal pain of great severity appearing in the first few days after labor, attended by pyrexia with abdominal distension and the other signs of beginning peritonitis, and the presence of a small uterine tumor, were common to all the cases.

The end and aim of treatment is, of course, the relief of the strangulation, and the means which should be adopted follow on the natural history of the accident.

An intramural fibroid has been nourished by vessels running through the soft and expanded wall of the pregnant uterus. After the delivery of the child, the rapid involution of the first few days of the puerperium decreases the size of the uterus—which may be regarded for the moment as the pedicle of the tumor—and thus so changes the relation of the tumor to its bed that its presence excites spasmodic contractions of the uterine muscles. These contractions partially cut off the venous return from the tumor, which thus becomes edematous and increases in size; this increase of size and pressure in turn increases the strangulation, and thus the vicious circle is formed.

The pain and the slight peritonitis—probably due to an exudation of serum from the surface of the tumor—are well recognized as a necessary result of the strangulation of any abdominal tumor; but it is important to remember that this differs from other strangulations in the fact that its cause is functional and intermittent, *i. e.*, it is due to the intermittent action of the muscular fibers which surround the tumor, and are excited into activity by its presence. For this reason the allaying of the irritability of these fibers by morphia, or better—and probably far better—their complete relaxation by anesthesia, at once puts an end to the strangulation for the time; and it is probable that the majority of the cases so treated will recover spontaneously, as in Cases 1, 3 and 4. When this happy result does not follow there can be no relief unless by the knife, as in Case 2.

In operative cases in which the situation of the tumor renders it inaccessible except by the abdomen, or in any case in which the inefficiency of the treatment by occasional anesthesia and morphia has been demonstrated while the patient is still in good operable condition, I should advocate an abdominal extirpation of the tumor, by myomectomy, or hysterectomy, as circumstances might render necessary; but when the tumor is easily accessible from the vagina, or even from the interior

of the uterus—as in many largely sessile tumors—and especially in cases in which a resort to the knife is not decided upon until the patient is nearly in *extremis*, I think well of some such procedure as that employed in Case 2, of which I wish to speak a little more in detail.

This operation though, so far as I know, previously untried, was naturally suggested by the nature of the lesion which had been diagnosed. It was evident that the increasing size of the tumor was due to a compression which was just sufficient to occlude the veins without stopping the influx from the arteries which supplied the tumor. It was also evident that this muscular compression was excited and continued by the pressure of the enlarged tumor on the surrounding muscular fibers. It seemed probable that if the retained serum were freely drained off and the tumor allowed to decrease rapidly in size, the contracting muscular fibers would be relaxed and free return of the venous blood be permitted. All these consequences apparently followed, as the result was immediate and exceedingly happy.

This subject is to me a new one. I have seen no mention of it in any text-book, nor even in periodical literature. No doubt many such cases have been seen by other men and perhaps reported spasmodically, but the subject seems to me to have received less attention than it deserves, and to be worth calling to the attention of the profession generally.

The possibility of the occurrence of this distressing and dangerous accident after parturition should, I think, be made an element in weighing the question of the necessity for removing fibroids by myomectomy from young married women.

#### CONCLUSIONS.

The diagnostic points are the following:

1. The appearance in the early part of the puerperium of severe, intermittent, paroxysmal pains bearing close resemblance to labor pains, and referred to a definite spot at which there is acute tenderness.

2. The appearance, after a few hours of these pains, of the symptoms of a pelvic peritonitis, and often in an alarming degree.

3. The detection on physical examination of an irregularity in the uterine wall at the tender spot, not necessarily of large size, and possibly to be made out only under anesthesia.

The principles of treatment should be:

1. The control of the pain by morphia, and if this is not promptly successful, by brief but profound anesthesia, which should be succeeded by relief, and should be repeated whenever the pain reappears.

2. If the preceding measures fail, and the patient is still in good operable condition, an immediate myomectomy is probably the best treatment.

3. If the condition has remained undiagnosed until the peritoneal symptoms are extreme and an abdominal operation will probably involve a high mortality risk, and if in this case the tumor is in any way accessible from below, its free puncture and the drainage of the contained serum may probably be relied upon to terminate the attack, and permit a safe removal of the tumor at a later date, should that be necessary.

**Quack Medicines in Germany.**—One of the measures adopted in the campaign against charlatantry being waged in Germany, is the publication in the medical journals of descriptions of the nature of the most widely advertised quack medicines.

## SYMPHYSIOTOMY.

PRACTICAL DEDUCTIONS FROM AN EXPERIENCE IN  
THIRTEEN CASES WITHOUT A DEATH FROM  
THE OPERATION.\*

EDWARD A. AYERS, M.D.

PROFESSOR OF OBSTETRICS, NEW YORK POLYCLINIC.  
NEW YORK CITY.

In complying with the request of the officers of this Section for a short paper on symphysiotomy it is my belief that the most acceptable handling of the subject would be such as best exploits the lessons learned through my own experiences.

I have performed symphysiotomy thirteen times upon eleven individuals, repeating the operation in subsequent pregnancies upon two women, the operation being done three times on one, she having had it done in the first instance by another physician.

Were I to have my obstetrical work to do over again I would refrain from symphysiotomy in one of the cases, selecting Cesarean section instead; I would perform symphysiotomy with less previous use of the forceps in three of these cases, and would perform symphysiotomy in at least ten cases in which it was not done.

Cesarean section was done in one case successfully, in which symphysiotomy would have done equally well, speaking from an *a priori* point of view. In a service of some 5000 confinements, partly indoor and partly outdoor, I estimate that there were about 25 cases which would have been suitable for symphysiotomy from a theoretical standpoint, had they been reached when in proper condition to justify the operation. The results in my cases have been as follows:

CASE 1.—Third pregnancy following craniotomy. Complete recovery from symphysiotomy; child still-born from prolapsed funis, due to shoulder presentation.

CASE 2.—Breech presentation. Cephalic version performed by another physician. Complete recovery from symphysiotomy done by the writer. Child still-born as a result of version and forceps efforts.

CASE 3.—Primipara. Delivery of twins following symphysiotomy. Complete recovery. Infants lived.

CASE 4.—Primipara 3 days in labor. Symphysiotomy, complete recovery. Infant lived.

CASE 5.—Second pregnancy. First child born dead after a week of labor. A vaginal cicatrix of great thickness limited the vaginal caliber to 2 inches diameter. Cicatrix was cut on both sides of the posterior median line. Symphysiotomy was next performed and child delivered in good condition. The pubic wound healed properly, but two sloughs from the cicatricial tissue caused vesico-vaginal and recto-vaginal fistulae. Puerperal and pneumonic sepsis ensued from bacillus coli communis infection. Patient died 33 days after delivery. Cesarean section should have been performed.

CASE 6. A primipara. Symphysiotomy was performed after hard use of the forceps. Complete recovery. Child lived.

CASE 7.—Third pregnancy following two still-births, one after forceps traction and the other after forceps, podalic version and traumatic separation of the body from the head by traction. Symphysiotomy performed in third labor. Complete recovery. Child lived.

CASE 8.—Eighth pregnancy. Two premature labors, two miscarriages, four forceps deliveries of living children. In present labor, forceps had been used unsuccessfully before I received the case. They also failed after extreme trial by me. Symphysiotomy performed. Complete recovery. Child lived.

CASE 9.—Second pregnancy. The first child was delivered dead after symphysiotomy performed by another physician. The second labor was completed by me after symphysiotomy. Complete recovery. Child living.

\* Read before the Obstetrical Section of the New York Academy of Medicine, April 25, 1901.

CASE 10.—Primipara. After severe forceps use symphysiotomy was performed and the child delivered in good condition. Complete recovery.

CASE 11.—Third pregnancy; both of the others resulting in delivery of living children after violent efforts, but both children dying shortly after birth. I delivered the third child after symphysiotomy in excellent condition. Complete recovery of mother barring a pinhole fistula which lay just anterior to the cervix. I attribute it to the abnormal condition of the cervico-vaginal tissues, which had been much injured in previous deliveries. Child lived.

CASE 12.—Same patient as Case 9.—Two previous symphysiotomies. Following hard forceps traction I performed symphysiotomy for the third time and delivered the child in excellent condition. Mother recovered completely.

CASE 13.—Eighth pregnancy. Two children living. Symphysiotomy performed after failure with forceps. Child delivered alive, but died quickly from over-use of the forceps. Complete recovery of the mother.

I afterwards delivered Cases 6 and 11 of living children without resorting to symphysiotomy. In each case the fetal head diameters were smaller than in the previous children.

Case 1 in a subsequent labor was in charge of another physician during my absence from the city. Podalic version, rupture of the uterus, and death of mother and child resulted.

Summarizing the results, I have operated 13 times without infection of the joint, and without a death due to the operation. Three children were lost and 11 saved. Perfect union of the pubes, that is, firm, fibrous union with a play of the joint of about one-eighth inch, has been secured in every case, except in Case 5, which died as above stated. Each patient was kept in bed four weeks. My method of operation was followed in all cases. Hemorrhage did not amount to more than three to four ounces at any time. No stitches were taken in any case. With the exception of Case 5 with the cicatricial vagina, there was no laceration of the vagina, bladder, urethra or peritoneum. No general disability has ensued. Moderate cystocele resulted in two cases, and bladder irritability lasted in most of the cases for four to six weeks. In no case has discharge from the wound occurred. In the last six cases the patients were placed in my symphysiotomy hammock bed, with marked improvement in comfort, cleanliness and ease of nursing.

A well-defined prejudice exists against symphysiotomy. This seems to be due to the dislike we feel to making wounds close to the vulva in labor, to the opening of a joint, to fear of hemorrhage that might be difficult to control, to fear of tearing the soft tissues around the symphysis, to fear of injuring the sacro-iliac joints, and to the dread of failure of union of the joint and consequent crippling.

This prejudice has been still further strengthened by two factors: 1, that the majority of operations have been undertaken only after severe efforts had been made to deliver the child with forceps, and 2, in about 90 per cent. of cases the operators' experiences have been limited to but one or two symphysiotomies.

In addition to the above, the general statistical results of the operation have, if taken at their face value, justified this prejudice, for a mortality percentage of between 9 and 10 is far from satisfactory. The true mortality can be had only after we have subtracted that due to all efforts at delivery which preceded the operation. The mortality from parturition is about seven-tenths of 1 per cent. From such cases as involve delay, version or forceps, and all objectionable features, difficult deliveries

in short, the mortality, outside Cesarean section, symphysiotomy or craniotomy, is surely in the neighborhood of 4 to 5 per cent. The onus of such efforts long falsified the truth regarding Cesarean section; and it is still giving a bad name to symphysiotomy.

I protest against the recent statement of Professor Reynolds, that, when the patient is of the "favorable class" Cesarean section should be the choice, and when the "unfavorable class" symphysiotomy should be preferred.<sup>1</sup> Nor do I agree with him in the statement, that the essential mortality in Cesarean section is as low as that of symphysiotomy. Properly, an operator should select that method which will give the best results, not in general, but in his hands; and he may be able to get better results with the unsafer method as compared with such results in general.

In briefly considering the sources of prejudice against symphysiotomy I am compelled to speak from the standpoint of my method of operation, as my experience is limited to that method.

1. Wounds About the Vulva.—The site of the small wound made just below the clitoris can be made absolutely aseptic, even though infection of the vaginal tract has already occurred. This wound is kept open for but a few minutes while the joint is being severed; and it is kept safe from infection during delivery by placing a wet antiseptic wad of cotton over it until final closure. No stitches are required, as the mouth of the wound is tightly closed by bringing the knees together, which closes the vulva, and by drawing the skin to the median line with transpubic adhesive strips. Anterior rotation of the trochanters further helps to close the labia over the wound. A soft-rubber retention catheter being left in the bladder and dropped down behind the thighs to the bed-pan, avoids any necessity of disturbing the wound after dressing the patient for bed.

2. Opening of a Joint.—The dangers from opening a joint depend primarily upon the ability to secure perfect technic in asepsis, and in avoiding exposure of the bone structure in case of suppuration. Notwithstanding many statements which I have noted to the contrary, I believe perfect technic and asepsis can be easily attained in the subcutaneous method of section of the symphysis. The latter is not a joint in the ordinary sense, as, while there is motion there is not any play of one surface over the other. It is more like the joints of the bodies of the spinal vertebrae in construction than sliding joints, having a cartilaginous plate interposed between the pubic bones. The osseous tissue should not be touched by the knife, although it may occur. But certainly it is much easier to secure perfect asepsis here than in a Cesarean section, and drainage and thorough irrigation are easily obtained if needed.

3. Hemorrhage.—It is simply impossible for hemorrhage beyond several ounces to occur, unless one stupidly passes the scalpel below the pubes instead of along its face, cutting the bulbi vestibuli, or pushes the knife up beyond the upper border into the peritoneal cavity. That which might result from laceration of the vagina must depend upon the judgment used as to the amount of disproportion between the fetal head and the pelvic caliber and the care employed to secure full dilatation of the cervix before operating, and that employed during delivery by the operator and the one holding the pelvic crests. Separation of more than  $2\frac{1}{2}$  inches should not be counted upon to secure passage of the head.

4. Peri-symphysial Lacerations During Delivery.—

To my mind the chief anxiety is felt over this feature in symphysiotomy. Section, hemorrhage, sepsis and postpartum disability combined scarcely cause as much anxiety as this feature, and I have tried to study its points accordingly. Symphysiotomy should never be undertaken until one has introduced his hand within the cervix sufficiently to directly palpate the fetal head and pelvic inlet, and so ascertained that a reasonable pubic separation,  $2\frac{1}{2}$  inches will secure delivery. Next, as I believe in immediate delivery after pubic section, it is very important to secure full antepartum dilatation of the cervix before operating for these reasons: When the pubes have been separated the bladder and anterior cervix and vagina lose their support and show a marked increase over normal in the tendency to drag down in advance of the head and below the pubes. The anterior cervix appears at the vulva and the bladder rolls around the sub-pubic arch unless prevented. If forceps traction is made with the cervix insufficiently dilated these soft parts are then drawn away from the post-symphysial attachments and thus lead to lacerations. While antepartum dilatation can not be artificially rendered complete, it should be fully approximated by hands or rubber bags; then, in using the forceps, the disengaged hand should press back the cervix and bladder while the forceps slowly and gently bring the head, not so much through the brim as through the cervix. When the latter has been slipped back over the head, the next aim, after the head has entered the pelvic basin, is to assist anterior rotation of the occiput with the forceps. The separation of the pubes alters the normal mechanism as to rotation of the occiput under the pubes, the tendency being for the head to remain in a transverse position. Continued care must be taken in delivering the shoulders, delivery of the anterior shoulder first being my preference.

That my method of operating is best for avoiding lacerations I believe, because by it there is less operative separation of the tissues immediately connected with the symphysis than by other methods, and, consequently, less weakening of their supports and fewer starting points for laceration. I have tested this question by comparisons on cadavers and satisfied myself that this view is correct.

5. Injuries to the Sacro-Iliac Joints.—Such injuries need not occur so long as selection of the operation regards its proper scope. Its avoidance is further secured by means of skilful harmony of action between operator and the one holding the pelvic crests, which means steadiness in traction and evenness in pelvic support.

6. Failure of Joint Union and Subsequent Crippling.—If failure of joint union after symphysiotomy were a matter of good fortune rather than the reward of care there would not be any symphysiotomists. The natural tendency under ordinary care and by various means of pelvic support is to good union. Under the best methods such union becomes a practical certainty.

The following are the requirements necessary to secure the surest and best results:

1. Constant apposition of the pubic bones with even coaptation, but without compression.
2. Ability of the patient to empty the bowels and bladder without disturbance of the pubic joint, and ease of cleansing the genital and anal regions.
3. Freedom of restraint of the body above the pelvis, and of the limbs, whereby lactation can be performed and the great discomfort of prolonged restraint avoided.
4. The avoidance of bedsores.

Considering that what we want is a guarantee, not a probability, of union of the joint, I believe the only sure method of treatment is one in which the pelvis is swung in a U-shaped hammock. I used sandbags in my first two cases and a patent bed similar to the Dupont or Herbert "elevation bed," strapping strips of adhesive plaster across the pubes and pelvic sides; but, while I secured proper union, as many others have done by various methods, there was constant risk that the bags might get displaced or the patient turn on her side and the joint coaptation thus become disturbed.

In my last seven cases I have used my hammock-bed, descriptions of which have courteously been incorporated in the text-books of Drs. Jewett, Grandin and others. I feel satisfied that its features meet all the requirements mentioned above satisfactorily, and particularly afford a guarantee of joint union with proper coaptation of the opposing bones. The only criticism which has been applied to it is that of non-availability, which is true in private practice, but not in hospital work. Where my hammock is not available I recommend Dr. Dickinson's canvas sling, which can be swung from the ceiling or a tripod, and which, like my hammock, represents the safest method of securing union.

The Question of Sutures.—If I believed that suturing of the pubic bones were necessary after symphysiotomy I would discard the operation in favor of Cesarean section. But there is not the slightest need of such procedure by my method of operating; not even suturing of the soft parts is required. Drilling and suturing the bones greatly adds to the objections to the operation.

Scope of Symphysiotomy.—It seems scarcely worth the while to go over the arguments in favor of one or the other of the four means of securing delivery in obstructed pelvic cases. Nearly all of us argue along the line of our own successes; and in one respect this is, if not logical, at least wise, for the best method in the individual case depends more on the special skill of the operator by one method than upon the results obtained in general. The *essential* mortality from Cesarean section and symphysiotomy is not now far apart, although I believe that of the former to be nearly double the latter. The difference in fetal mortality is, of course, favorable to Cesarean section. The practical advantage between Cesarean section and symphysiotomy will depend upon the operator.

The most influential point affecting the results is the performance of the operation selected when the patient is in a favorable condition. This one point affects the results in general probably 50 per cent. For myself I grant symphysiotomy the following scope:

1. Mensural; obstructed delivery due to pelvic incapacity.—Where separation of the pubes is limited to  $2\frac{1}{2}$  inches to secure passage of the head, its availability is not easily ascertained, and we must consider the shape and dimensions of the pelvis and head. With equal length of the conjugata vera in different types of pelves a greater pubic separation is necessary in one form than in another.

The justo-minor pelvis requires a relatively wider separation than others, as gain in dimensions is secured entirely by the separation. Further, the "masculine" type of justo-minor pelvis, with its thicker bones, which encroach upon the caliber, will require more separation than the "juvenile" form with thinner bones.

The obliquely contracted, or Naegele pelvis, requires a relatively lesser separation, as the caliber is greater than in the justo-minor, and becomes utilized by the

head after pubic separation. To illustrate my meaning: If the right half of the pelvis is contracted but not the left, and the fetal head presents in a left occiput transverse, when the pubes separate the occiput moves snugly into the left half, slightly rotating posteriorly, with the right brow pressing into the inter-pubic space. In this way what might be called the normally inutilized space just to the side of the promontory is taken up and offsets the loss in caliber of the right half of the pelvis to some extent.

The narrow, funnel-shaped pelvis requires the least separation relatively, as the separation of the pubic bones, which is like the swinging open of double gates set somewhat out of the perpendicular, secures the fullest effect in increasing the transverse diameter. One-inch separation of the pubes increases the middle transverse diameter at the brim a fraction over one-half inch. The flat, rachitic pelvis, with its projecting promontory and narrow conjugata vera, occupies a place midway between the justo-minor and the narrow-transverse pelvis. The contracted outlet pelvis likewise occupies a middle place.

As symphysiotomy is an operation that should never be determined upon until a patient is in active labor, and as it requires but a few minutes to properly prepare for it, the actual test of the question of its adaptability for securing passage of the head is and should be made during labor and while the patient is anesthetized. Due regard must be given to the previous history in multiparæ and to palpation, pelvimetry, Müller's test, and, if we like, to cephalometry by Perret's method in both primiparæ and multiparæ; but one is neither justified in making a final decision nor required to do so previous to the stage of fair cervical dilatation and moderate test of both automatic engagement of the head and artificial effort with the forceps. An exception might be made to this that it would not be desirable conduct in view of the selection of Cesarean section when it was found that too much separation would be required to justify symphysiotomy. My answer to this would be that pelvic contractions to such degree as demand Cesarean section constitute an exception, as they can be determined before labor.

2. Symphysiotomy is justifiable in certain mal-presentations: Impacted posterior occipital, and chin presentations, in which the fetal pulse is good and delivery is not possible without mutilation.

The operation should give place to premature delivery when the forecast of impossible delivery without major operation is sure and the patient prefers it, or the physician is not accustomed to major operative work. It should give place to Cesarean section in cases in which there are obstructions to vaginal delivery by tumors, exostoses, cancer and pelvic contractions greater than the rule given above allows for symphysiotomy.

The great majority of cases of pelvic contraction beyond the scope of forceps delivery lie within the range of symphysiotomy. In some forty cases of such contractions occurring in my clinical experience, and observation of others' work, there was not one which could not have been delivered by symphysiotomy; and in only one case was Cesarean section positively indicated.

23 West Fifty-third Street.

**Novel Post-graduate Course.**—The medical officials in the duchy of Hesse were taken on a trip to Hamburg instead of having the usual course of post-graduate lectures. All the sanitary and hospital arrangements of the city were inspected under the guidance of experts.

## Clinical Report.

### FEVER OF HODGKIN'S DISEASE.

CARL C. WARDEN, PH.B., M.D.

Professor of Anatomy and Operative Surgery in the University of Nashville.

NASHVILLE, TENN.

The "Note on the Fever of Hodgkin's Disease," by Dr. J. H. Musser,<sup>1</sup> has led me to report a case that, while it does not conform rigidly to a definite type of Rückfall fever, presents many characteristic points.

The case is that of a lady, 30 years of age, married, mother of three healthy children. Up to the present illness she had enjoyed good health. Her family history was negative. In the fall of 1898 she complained of weakness, malaise and swelling of the cervical glands. She was treated for malaria and spent the winter of 1898-9 in Florida. She stated that she had fever "off and on." Early in 1899 she had a febrile attack that persisted for some weeks. During that time the cervical glands on the left side and the inguinal glands on both sides became enlarged and tender. Upon subsidence of the fever the glands became reduced in size and less tender. In May there was another lighting up of the fever accompanied by growth and induration of the glands, but under Fowler's solution the pyrexia again subsided and the glands softened and diminished in size. All medication was suspended June 19. The temperature remained normal until June 26. The duration of the apyrexial period was about 16 days. From June 26 until July 30 there was a pyrexial wave reaching its fastigium about July 15, when the systematic record of temperature was begun.

From July 30 to August 10 the temperature hovered about normal with slight daily elevations and intermissions. Then followed an afebrile stage lasting three days. During the decline of the paroxysm the patient improved rapidly, the glands diminished in size, the color improved, the appetite became urgent and she was out of bed and going about the house. On August 14 the fever returned, and during the time between that date and the date of her death, September 30, there occurred three distinct paroxysms but with remissions only between. The temperature curve showed morning remissions and evening exacerbations as a rule, but there were observed scattered instances of a reversed type.

The record of the temperature and the amount and distribution of the glandular involvement may be seen in the accompanying diagrams. This case illustrated fairly well the tendency of the fever to recur in waves separated by an interval of calm. With the progress of the disease the waves increased in frequency, with lulls more brief between them. Repeated blood examinations showed no variation from the normal beyond a slight leucocytosis, noted but once, and oligocythemia toward the close. Late in the progress of the case there was considerable pain in the left arm, chest, right side of the abdomen and in the right hip and thigh, all easily accounted for by pressure effects. The liver and spleen were moderately enlarged. An autopsy could not be obtained.

Dr. Musser's paper is an important and valuable communication. The writer has seen four cases of Hodgkin's disease in Nashville during the past four years; in two the course was characterized by fever and two were seen for a brief period only and subsequently were lost sight of. Only in the case reported were there opportunities affording a partial study of the temperature.

1. American Medicine, Jan. 4, 1902.

**Fecal Matters in Urine.**—Desesquelle writes to the *Bulletin des Sciences Pharmacologiques* that the discovery of fecal matters when urine is being examined in case of cystitis, should not always be attributed to contamination of the receptacle, but should suggest the possibility of vesico-intestinal fistula. He mentions three cases in his experience in which the etiology of a rebellious cystitis was explained by the discovery of traces of fecal matters in the urine, when nothing previously had indicated such a possibility.

## REGENERATION OF NERVES.

The healing of nerves is a subject of much scientific as well as actual, practical interest. At the present time most investigators hold that when a peripheral nerve regenerates, either after division or degeneration, the peripheral segment undergoes "neurotization" from the end of the proximal portion. This means that the ends of the axons above the point of division or degeneration grow out into the distal part of the nerve, the continuity of which is thereby restored. Clinical surgery teaches that this process may require weeks and months for its completion. But there is another view, at the present time held by a small number only, which teaches that in nerve regeneration axons, medullary sheaths, and neurilemmata are formed from cells in the distal segment, called neuroblasts, and that the fusion of the different parts thus produced with one another and with the central part restores the continuity of the nerve trunk. This theory, which may be called the peripheral theory, is not in harmony with our present conception of neurons, each of which is regarded as a complete cellular unit capable of regenerating its lost parts, at least within certain limits.

The most recent investigation in nerve regeneration is by the two Englishmen, Charles A. Ballance and Purves Stewart,<sup>1</sup> whose numerous experiments gave results that in their view are reconcilable only with the peripheral theory of regeneration. Ballance and Stewart find that when a nerve trunk is divided the axons and myelin sheaths soon suffer a fragmentary disintegration followed by absorption, which eventually extends throughout the entire nerve distal to the point of division, while in the proximal end there is only limited degeneration, the cut fibers curving back and forming a more or less distinct bulb-like swelling. The subsequent regenerative changes take place in about the same manner whether or not the cut ends are united by suture or other means. The cells of the neurilemma take on active neuroblastic function and produce short lengths of axons and myelin sheaths, which, linking themselves together, form continuous nerve fibers. At first the new sheaths are beaded, due it is thought to the presence at more or less regular intervals of cells which produce the myelin. Finally, the cells become less conspicuous and are recognizable at the internodal points only. In the scar tissue that always forms between the

ends of a divided nerve, the new sheaths increase in number from above downward and not from below upward as would be the case did the new sheaths represent downgrowths of the old. In transplantation experiments the engrafted nerve acts as a scaffolding for the invading neuroblasts which enter chiefly by the side of new blood vessels. As regards the axons, our authors state that from the appearances obtained by various methods "it is clear that regeneration of axis cylinders does not take place by a process of outgrowth from the proximal segment, but is commenced and completed by the activity of cells already existing in the trunk of the nerve." As stated, the junction of the proximal and distal segments of a divided nerve is not essential for the regeneration of axons in the distal part, but the axons that form under such conditions do not attain maturity. As the proliferating neurilemma sheaths finish their activity as producers of myelin and axons they arrange themselves in columns and coalesce into new neurilemmata enclosing the newly-formed myelin, which in turn is wrapped around a new axon.

Such in brevity is the manner in which nerves heal, according to the English investigators. They regard the peripheral nervous system as composed of chains of neuroblasts fused to form neurilemmata, myelin sheaths, and axons. The limited degree of regeneration of axons in the central nervous system, as seen, for example, in hemisection of the cord, they would explain as dependent upon the absence here of neurilemmata, which are of fundamental import in regeneration of axons and myelin sheaths. The neuron theory must be abandoned, because it is not in harmony with the facts observed by them in the healing of peripheral nerves. In the literature are several examples of early return of sensation after secondary suture of divided nerves. Jessop, Langenbeck and MacCormac have recorded cases of secondary nerve suture in which sensation returned on the eighth day, the seventh day, and the same day after the operation, and other cases of like nature might be cited. Ballance and Stewart point out that this early return of sensation after secondary suture is easily explained on the score of "peripheral regeneration" of nerves, the secondary suture restoring the conductivity of the otherwise quite fully regenerated parts. But there are many conflicting statements in the literature in regard to the early return of sensation after secondary suture, and it is noteworthy that there is no early return of motion under similar conditions; for this reason much weight can not be attached to the significance of the early return of sensation after secondary suture in its bearing upon the mode of regeneration.

Without attempting minute criticism of the work of Ballance and Stewart, it may be permissible to point out the general fact that the peripheral degeneration distal to the point of division of a nerve does not harmonize well with the theory that regeneration is accomplished by the neurilemma cells taking on neuroblastic

1. The Healing of Nerves, London, 1901.

functions. If these cells have the power to form pieces of axons and medullary sheaths, at first discontinuous, it becomes rather puzzling to attempt to discover any good explanation for the degeneration that follows division. It rather would seem that the peripheral end, if of peripheral origin, might maintain its vitality at least for a time even though its connection with the central neurocytes is severed. On the other hand, degeneration after nerve division is easily understood when we regard the neuron as a functional, nutritive and anatomic unit. Further investigations are necessary before the neuron concept now in vogue is materially modified.

#### FUNCTIONAL ATHYROIDISM.

The impression is gaining ground that besides disease-conditions due to absence of the thyroid gland or total inhibition of its secretion, there are also functional deficiencies of thyroid secretion that produce recognizable symptoms. These symptomatic conditions have proved utterly obstinate to treatment, as a rule, up to the present time because of failure to recognize their cause. Two recent contributions to the subject show that the therapy of these conditions is very encouraging when their true etiology is recognized and that the diagnosis is not difficult if suspicions of the nature of the fundamental disturbance of metabolism are aroused. The therapeutic test of the administration of thyroid extract and its good effect makes the diagnostic conclusions absolutely certain.

Dr. Heinrich Stern<sup>1</sup> recently called attention to the fact that juvenile obesity is not infrequently accompanied by a tendency to tachycardia, with symptomatic dyspnea on exertion. These conditions are more common among females than among males. Not infrequently there is an associated chlorotic tendency. This set of symptoms seems to depend on faulty function of the thyroid or parathyroid glands. It has been noted often before that thyroid extract frequently proves beneficial in cases of the adolescent obesity that sometimes sets in just after puberty. About this time the thymus gland disappears and the thyroid gland takes on special developmental activity. Any interference with normal development is sure to be felt in the general metabolism. The thyroid enlarges proportionately more in females than in males at this time, and all through the subsequent life this gland is evidently more intimately related to metabolic processes of various kinds and especially with sexual manifestations than in the male. It is not surprising, then, that these conditions which result from lowered function of the thyroid, obesity, nervous symptoms, and at times chlorosis, should be seen rather frequently in the female. The therapeutic test of the good effect derived from the administration of thyroid extract would show that the presumed etiology is correct.

At the October meeting of the Harvard Medical Society of New York City, Dr. J. G. Perry called attention to a set of symptoms also presumably due to de-

ficient thyroid secretion that improved under the administration of the gland over prolonged periods. This last characteristic of prolonged tolerance to thyroid medication is of itself an absolute index of thyroidic disturbance of metabolism, since symptoms of intolerance develop very soon in the normal individual. In Perry's cases four symptoms were practically always present. They were: 1, a tendency to obscure painful conditions of the joints somewhat resembling the neuro-pathic joint pains described by Charcot and grouped under the term neuro-arthropathy; 2, persistent headache for which no direct cause can be found; 3, a weak and rapid heart; and 4, in women—a marked menorrhagia. In one series of cases described, these symptoms were noted in three generations of the same family. In the grandchild there was a distinct associated myxedemic tendency that promptly grew better under the administration of thyroid extract.

It would seem, then, that though the mystery of thyroid chemism remains almost as obscure as ever, we may yet be able to base rational therapeutics of functional athyroidism on clinical experience. It is not the first time in the history of medicine that clinical teaching has led scientific theory. Great care is needed to avoid self deception in such matters, but the field is most promising for empirical applications of clinical indications. The success so far attained encourages the hope that further experience may add still more to practical knowledge on the subject.

#### THE DAWN OF FRATERNAL UNITY.

We are too apt to take a pessimistic view of things in relation to the medical profession; we are so conscious of our failure to be what we ought, or what we would like, to be that the gloomy aspect often unduly colors our outlook on medical conditions. It is not altogether bad if it but makes us duly modest and causes us to strive for more satisfactory conditions, but it is well to occasionally look on the bright side. There are many reasons for this and we believe never more than at present.

The address of Dr. Foshay<sup>1</sup> in this issue is in this tone and, while it is of special local interest, it will also interest many in every part of the country. It points to a new era in medicine, not one to come at some future time, but a new era that has already dawned. We do not refer to the new conditions which Foshay mentions, wherein medicine has arisen from the domain of empiric art to a fixed position among the applied sciences; nor to the broadening and liberalizing influence of the higher education that is beginning to be felt; nor yet to the bright hopes of the physician's greater usefulness in the future from the rapid increase in scientific knowledge in every branch of medicine. All these indicate a new era in medicine, which promises a higher good for the people and a future for medicine encouraging in every way. But the particular thing to which we

1. See THE JOURNAL A. M. A., Feb. 15, p. 447; also p. 474.

1. See page 625.

refer points to a new era in the profession itself; to a fraternalism that has in the past been none too much in evidence, to a spirit of self-sacrifice and a banding together for mutual good. That the address was timely and found the ground prepared for its recommendations is the best evidence that the new era of fraternity and combined effort is at hand. What is true in Cleveland is true elsewhere, more true now, we believe, than at any time in the past; the profession is ready to become a united body, to drop its bickerings and work for the good of all. In no other profession can this be done more appropriately, for in no other are the local and professional interests so closely allied in every way to the public good. We have no need to sacrifice any of our high traditional ideals; these are all in the line of progress we wish to follow. That they have not been enough our guides in the past is the reason for the evils that have existed and of which we now begin to see the end.

What a united profession can do needs hardly to be told and yet the good it can accomplish may be more than our fancy can at present compass. First of all it will command public respect and esteem more than ever before and this alone is the key to much of what we need. An influential medical profession, respected for qualities that no one can overlook or honestly depreciate, will be the only possible successful bulwark against the multiform manifestations of quackery. It can not be exploited to its disadvantage by unprincipled commercialism. Even should the socialistic ideals be realized at some future time the profession will still be one of the right hands of the State, the indispensable adjunct of the civilization of the day. We are not looking for a medical millenium, for whatever the order social evolution may take, everything will be at our command if we march as a united body on the road upon which we have entered. As Dr. Foshay says, we are living in the most wonderful period of the history of medicine, but it largely depends upon our union and harmony in work, as well as upon our scientific spirit, to make the present only an adumbration of what will be realized by our successors.

#### ALCOHOL A DANGEROUS FOOD.

It seems to be the fashion to commend alcohol as an article of diet. Text-books on physiology, university professors, authors of papers before medical meetings, all have their say on the subject and their words are taken up by the reporters and given to the newspaper-reading public not at all diminished in the strength of their endorsement of this agent. We call it a fashion, because just at present there seems to be an unusual amount of literature devoted to the subject. Indeed, this has been noticeable, since Professor Atwater gave his opinion that alcohol is a food. He was, however, much more guarded in his statements than many that have followed him. In fact, if we accept only his dictum that it is a food, but one that a healthy man can

better get along without, it would seem that the less we say of its purely nutritive value the better. Some of the later utterances, however, are that alcohol in moderation harms no one, but is actually beneficial. Much of this is undoubtedly the reaction caused by extreme statements on the other side, but it is not exactly becoming for scientific men to be thus influenced. The question whether or not alcohol is a food is largely an academic one; except when prescribed for pathologic conditions it rarely if ever fills the place of a food. There is good testimony, not yet controverted or even contradicted, that comparatively small doses of alcohol have a direct deleterious action on the nervous functions and the capacity for work. We should not ignore these facts in the discussion of the safety or value of this agent in the normal human system, any more than we should ignore its occasional usefulness in conditions of disease. We may admit that it seems to add to the enjoyment of life for many individuals and yet we question its real benefit. Everyone admits that excess in alcohol is bad, but a large proportion of the population seems to find its happiness in such excess.

We believe that the consensus of the best medical opinion of to-day is that alcohol, while a valuable medicine in some conditions—and here many would include a limited dietetic value—is not properly a food. It is not what the Germans call a *Nahrungsmittel*, but is a luxury and a perfectly non-essential one to the healthy normal individual. The need of moderation in the use of alcohol and the difficulty in drawing the line between moderation and excess, together with the habit-building tendency, have all to be considered. The worst thing about the present tendency to say a good word for alcohol, is the certainty that whatever may be said will be utilized unscrupulously by advocates of the liquor interest. Give them an inch and they will take a mile, and some of our confrères have had good reason to regret this fact. We believe it will be found far safer for medical men to stand on the facts opposing the general use of alcohol than to even qualifiedly advocate its usage, except exclusively as a medicine and under medical prescription. Its cause is not one that requires any fostering by our profession.

#### TETANUS AFTER INJECTIONS OF GELATIN.

The recent outbreak of tetanus in St. Louis following the injection of faultily prepared and contaminated diphtheria antitoxin, and the occasional development of tetanus after vaccination are only too striking an illustration of the grave dangers that may lurk in otherwise not only harmless but beneficial and even life-saving procedures. Physicians can not be keenly enough alive to the fact that the cause of tetanus, be it the bacillus or its toxin, may find its way into the human body under the circumstances mentioned. Recently, cases of tetanus have developed after injections of gelatin—Gerulanos, Georgi, Lorenz.<sup>1</sup> In all these cases (four)

1. Deutsche Zeitschrift für Chirurgie, Bd. lxi. Abstr. in Centralbl. f. Bakt., 1902, xxxi, Feb. 2, 1902, p. 112-113.

the gelatin was injected for the purpose of arresting hemorrhage after severe operations in connection with existing lesions, such as subphrenic abscess and disease of the urinary tract. In one case a small abscess developed at the point of injection; the pus from it caused tetanus in a rabbit. In the other cases the connection between the injection of gelatin and the tetanus does not seem to have been proved by scientific methods, but the relation was so close that the observers report the cases as examples of tetanus after injection of gelatin. In one of the cases the hemorrhage was so threatening and severe that the solution of gelatin was injected "without sufficient sterilization." Recent experimental tests made at Strassburg proved the presence of tetanus germs in four out of six samples of gelatin.<sup>2</sup> Experiences such as those referred to in the foregoing carry with them the warning that practitioners can not be too careful in their sterilization, even when it concerns so insignificant an operation as a puncture of the skin.

#### THE VALUE OF ANTIDIPHThERIC SERUM.

Judgment on the value of Behring's antitoxin can not fairly be made from individual impressions of what might have been the course of this or that case of diphtheria if antitoxin had or had not been given, because the possibilities in any given instance are incalculable. Observation and comparison of a long series of cases under as nearly as possible equal conditions reduce the chance of error to a minimum and so form the only safe basis for opinion. When a large number of cases can be collected, the principles for judging the efficacy of antitoxin remain the same as when Roux in 1894 published his celebrated clinical investigations: 1. The disease must be pure diphtheria, bacterially verified. (Antitoxin has no effect on streptococcic membranous croup and but slight effect when there is mixed infection.) 2. The antitoxin must be of definite strength and be given in adequate dosage. 3. The duration of the disease before treatment must be taken account of in estimating the probable effect of antitoxin. Reports which cover the above eminently fair points, unanimously agree in demonstrating the great life-saving qualities of antitoxin when given early and in sufficient dosage. Extensive experiences in the Boston City Hospital,<sup>1</sup> for instance, show in every way wonderful effects from initially injecting 4000 units and repeating every four hours if necessary. The careful statistics of the Chicago Health Department show 8 per cent. of the total number of bacterially verified cases treated on the first day of the disease with a case-mortality of .42 per cent., 24 per cent. treated on the second day with 1.5 per cent. mortality, 35 per cent. on the third day with 3.5 per cent. mortality, 18 per cent. on the fourth day with 11.3 per cent. mortality, 13 per cent. treated later with 23 per cent. mortality. In giving a prognosis or in calculating what part antitoxin played in the outcome of any case it must be remembered that with or without this remedy the prognosis is progressively better for every year childhood advances. Including all cases over 15 years of age treated with antitoxin the death rate is not larger than 3 per cent. The harmlessness of pure anti-

toxin being abundantly proven and the facts being substantiated that most cases which look like diphtheria clinically are true diphtheria and grow graver in prognosis during every hour left untreated, it follows that it is the safest plan to adopt the advice of the many authorities who early use antitoxin in every suspected case.

#### POISONS AND DEFECTIVE RENAL ELIMINATION.

In cases of diseased kidneys where elimination through the renal secretion is more or less interfered with, it has usually been stated that poisonous medicines should be administered with more than usual caution for fear that they might accumulate in the blood and cause fatal effects. Such statements have generally been founded upon theoretical and not experimental considerations. For a long time opium was withheld in cases of uremia and other conditions associated with diseased kidneys because of fear that the lessened elimination would lead to poisonous results from the accumulation of the drug in the body. Although Loomis was not the first to employ hypodermic injections of morphin for the cure of uremic convulsions, it was he who especially pointed out the value of such treatment, and his advocacy of it has been largely instrumental in leading to its general adoption. Most clinicians now employ morphin in uremic convulsions without fear of bad results and with confidence that good will follow its use. In this instance the fear which came from false theoretical conclusions was overcome by the practical results of actual experience. Meltzer and Salant<sup>1</sup> have recently published the results of an important study of the effects of strychnin in rabbits after the removal of the kidneys. They have shown that less than the smallest fatal dose—"subminimum"—of strychnin may be administered subcutaneously at proper intervals to rabbits from which the kidneys had been removed without any resulting reaction, although large fatal doses of strychnin are apparently accumulated in the body. Several hypotheses are advanced to explain these phenomena, but none has yet been demonstrated experimentally. Knowing that strychnin is eliminated by the kidneys under ordinary circumstances, it was not unnatural to infer that the removal of the kidneys would lead to an accumulation of the poison in the body with resulting deleterious effects. These experiments show that such is not the case, either because of vicarious elimination assumed by other organs or for other reasons. Similar phenomena are observed when urea is excreted by various organs in cases where the renal tissue is largely destroyed by disease. The observations of Meltzer and Salant show how unsafe it is to conclude that the removal of an organ or the destruction of its function results in the accumulation in the body of the materials usually eliminated by it. In such cases the wonderful power of the remaining tissues and organs to assume the functions of those parts which are removed or rendered inoperative, must not be forgotten. The fear that cumulative effects may result if poisons are administered in the usual doses in cases of diseases of the kidneys has no experimental foundation.

## Medical News.

### CALIFORNIA.

**"Dr." Minnie Wells, Los Angeles,** has been convicted of practicing medicine without a certificate from the State Board of Medical Examiners, and has been fined \$300. This is her second offense.

**German Hospital.**—A hospital, to cost \$25,000, is to be erected by the First German M. E. Church of Los Angeles. The building will contain 30 rooms and work will be commenced on it by or before May 1.

**College Anniversary.**—The sixth anniversary of the College of Physicians and Surgeons, San Francisco, was celebrated with a banquet, February 25, at which Dr. Winslow Anderson spoke of the history of the college and addresses were made by members of the faculty and undergraduates.

**Berkeley Hospital.**—Although the directors of the Berkeley Hospital Association have decided to abandon their project of erecting a hospital, the Prytanean Society of the University of California will, in a measure, carry out the original plans by either erecting a hospital building on the campus or endowing a free room in one of the Oakland hospitals.

### DISTRICT OF COLUMBIA.

**Transfer of Hospital Control.**—Commissioner Macfarland has approved the report made by the Board of Charities upon Senate bill 3363, to transfer the control of the Government Hospital for the Insane, the Freedmen's Hospital and Asylum, and the Washington Hospital for Foundlings to the Interior Department. The Board of Charities reported against the passage of the bill, claiming that such a law would be a step backward in the establishment of the present department of charities.

**Medical Society.**—At the recent meeting of the Medical Society, Dr. Johnston's paper on grip pneumonia was discussed and Dr. Kober read one on the causation of disease. Dr. Lamb presented specimens and gave the histories of vegetating endocarditis. Drs. Woodward and Lamb jointly presented specimens and gave the history of cases of hemorrhage of the liver in the newborn. The smoker held on the 13th inst. was a success, almost every member of the Society attending and taking part in the relaxation. This was the first smoker ever given by the Society and its success will assure its adoption as an annual feature.

### ILLINOIS.

**Fifty-four Years in Practice.**—Dr. William W. Burns, Polo, now in his 81st year, has been in active practice for fifty-four years.

**St. Joseph's Hospital Ready.**—St. Joseph's Hospital, Elgin, which has been turned over to the Franciscan Sisters, has been fully equipped and is ready to receive patients to-day.

**Banquet to Dr. Helm.**—Dr. Clinton Helm, Rockford, was tendered a banquet, February 25, by the Winnebago County Medical Association, at the Nelson House, Rockford, in honor of the semi-centennial of his entry into practice. Dr. Daniel Liehty served as toastmaster, and among the speakers were Drs. David B. Penniman, Argyle; Thomas N. Miller, Rockford; Thomas H. Culhane, Rockford; John F. Snyder, Monroe Center; Emil C. Dudley, Chicago; Robert W. McInnes, Belvidere; Frank H. Kimball, Rockford; Ernest C. Helm, Beloit, Wis.; E. Wyllys Andrews, Chicago, and Clinton Helm.

### Chicago.

**Dr. Hugh T. Patrick** sails for Europe on the *Kronprinz Wilhelm* to-day. He expects to remain abroad for four months, returning about July 1.

**"Dr." Mabel Jackman** was fined \$100, February 22, for illegal practice of medicine, the evidence being secured by two employes of the State Board of Health.

**Dr. Fenger Ill.**—We regret to learn that Dr. Christian Fenger is seriously ill with pneumonia at his home. Drs. Billings and Favill are in attendance and report slight improvement.

**Attending Skiagrapher.**—The County Board has elected Dr. Harry J. Haiselden attending skiagrapher to the County Hospital; he will have charge of the x-ray apparatus recently installed there.

**For Poor Consumptives.**—Mr. Charles L. Adams has given \$30,000 for the purpose of erecting a home in Denver for needy consumptives, and has promised \$20,000 additional provided a

second \$20,000 is secured. The new home will bear the name of Mr. Adam's wife.

**Cook County Clinical School.**—In order to provide suitable conditions for rapid growth of the laboratory recently established at the County Hospital, the county officials have decided to incorporate the laboratory and museum into a school, the management of which is placed in the hands of the warden, the president of the county board and the superintendent of public service.

**In Charge of Dunning.**—Dr. John R. Neely has been chosen to take up the work of placing the county institutions at Dunning on an improved basis, and has been made medical director. He assumed charge, March 1. It is announced that the medical staff will be reorganized and increased to twelve, and that the number of nurses and attendants will also be increased. Dr. Neely is well fitted for this work, and has already won laurels by the excellence of his work in the Surgeon-General's office in Washington, and in the Department of Health of Chicago.

**Campaign Against Smallpox.**—Several of the railroads entering Chicago have endorsed the plan suggested by the Department of Health for preventing the spread of the disease. This comprises the following features: Vaccination for all employes and reports on the results; immediate notification by conductors when smallpox or suspicious illness is discovered on trains; notification by station agents of cases in their locality; reports by local railroad surgeons on their districts and instructions to them to push the propaganda of modern methods of vaccination; the distribution at stations of the Health Department's "Vaccination Creed," and other literature of that sort; the provision of facilities for disinfection, and the establishment of a central bureau of information in Chicago.

**The Health and Deaths of the Week.**—Twenty per cent. more deaths were recorded by the Bureau of Vital Statistics of the Health Department for the week ended March 1 than the week previous and 46 per cent. more than in the corresponding week of 1901. The exact figures are 434 one year ago, 529 the week before last, and 634 last week. The annual rates per 1000 of population are 12.87, 15.14 and 18.15, respectively—this latter figure being unpleasantly near the average New York mortality rate. For this city it is the highest on record for the season of the year. The causes of death showing the greatest mortality as compared with the previous week are—with the exception of pneumonia—the chronic diseases, and the result is seen in a 20 per cent. rise in the deaths of the aged, those over 60 years. Nervous diseases show 72 per cent. increase; consumption 46 per cent.; pneumonia nearly 35 per cent.; Bright's disease nearly 32 per cent., and diseases of the heart 30 per cent. There were 16 suicides and 36 other violent deaths—an increase of 53 per cent. over the number in the corresponding week one year ago and of 85 per cent. over that of the previous week.

### IOWA.

**Eleanor Moore Hospital, Boone,** was formally opened with appropriate exercises, February 17.

**Hospital Fund Grows.**—The fund for the new hospital to be erected at Marshalltown by the Sisters of Mercy now amounts to \$8000.

**William Woods Hospital.**—Mrs. Phebe Ann Cole, Osage, has deeded her property in that city to nine trustees, to be used as a public hospital. It is to be known as the William Woods Hospital in memory of Mrs. Cole's deceased brother.

**Personal.**—Dr. R. F. Raines, Arcadia, has located in Dixon, Ill.—Dr. Alonzo E. Rodgers, Tipton, has returned to his old location at Stratford.—Dr. Charles O. Grimes, Hayesville, has located in Harper.—Dr. W. Herbert Linder has moved from Stratford to Story City.—Dr. Sylvester L. Clabaugh, Yorktown, has moved to Bedford.—Dr. Joseph H. Sams, Clarion, has been appointed a member of the State Board of Health, vice Dr. John C. Schrader, Iowa City.—Dr. Louis M. Coon, Arion, has gone to Southern Kansas.—Dr. Park A. Findley, Des Moines, has been appointed first lieutenant and assistant surgeon in the Army, and has been ordered to Fort Leavenworth.—Dr. Owen S. Townsend, Blockton, has gone as a medical missionary to China.—Dr. Norman S. Craig, Manchester, has moved to Jennings, La.—Dr. Fred J. Raven, Mason City, has located in Grinnell.—Dr. John V. Littig, Davenport, has gone to Europe.—Dr. T. A. Kreuser, Chicago, has located at Calmar and will also have an office in Decorah.—Dr. W. P. Burke, Iowa Falls, has gone to Europe for a year of post-graduate study.—Dr. William N. Hurst, Blakesburg,

has moved to Oklahoma.—Dr. Anthony H. Verwerk, Bancroft, has located in Burlington.—Dr. Charles E. Todd, Oskaloosa, has moved to Los Angeles, Cal.

#### MARYLAND.

**Annapolis Emergency Hospital** has been incorporated.

**Militia Surgeon.**—It is reported that a bill has been reported favorably by the House, "providing for the appointment of a surgeon to state militia."

**Fund for Johns Hopkins.**—The women have started a fund for the benefit of the Johns Hopkins University. It is proposed that every woman in the state contribute one dollar.

**Mortality.**—For the week ended March 1 the deaths in Baltimore were 201, pneumonia leading with 35, followed by consumption, 19. During February there were 194 deaths from pneumonia.

**Dr. William Osler**, Baltimore, lectured at the University of Maryland, February 28, on the "Religio Medici" of Sir Thomas Browne, exhibiting nearly all the editions of his works and showing lantern pictures.

**Personal.**—Dr. Jesse C. Coggins, of the staff of the Maryland Hospital for the Insane No. 1 has returned from a visit to the European hospitals for the insane.—Dr. William J. McDowell, Baltimore, fell on the ice, February 21, and broke his left arm at and above the elbow. The injury is said to be serious.—Dr. S. A. Keene, Baltimore, has been appointed assistant superintendent of public buildings in charge of the court house at a salary of \$1200. Dr. Bernard P. Muse has been appointed assistant medical inspector, with a salary of \$500, vice Dr. Keene.—Dr. R. R. Crothers, Elkton, Cecil County, had a paralytic stroke, February 21.—Dr. J. Williams Lord, Baltimore, has returned from Cuba.

#### MASSACHUSETTS.

**Emergency Hospital Opened.**—The Boston City Hospital relief station at Haymarket Square was opened for service, February 20.

**Brockton Hospital Donations.**—The endowment fund of the Brockton Hospital has been increased \$15,000, of which \$10,000 was donated by Mr. Daniel S. Howard and about \$5000 received from the George O. Stevens estate.

**Keep Memorial Hospital.**—Mrs. J. W. Keep has offered to erect and equip a building in memory of her husband on the Westfield Hospital grounds, at a cost of not exceeding \$15,000 for the care of contagious disease patients, to be known as the Keep Memorial Building.

**Millions for Harvard.**—Harvard University Medical School needs \$4,950,000 to carry out the plans projected. Of this all but \$294,000 has been contributed and the trustees still have four months in which to secure the balance. Mr. James Stillman, New York, has contributed \$100,000, and the faculty has subscribed \$75,000.

**New Salem Hospital.**—The Hospital Association of Salem is about to erect 12 new buildings, which will accommodate 100 patients. The completed hospital will consist of an out-patient department and accident ward, maternity and children's ward, men's surgical ward, men's medical ward, women's surgical ward, women's medical ward, operating wing, annex wards, and a two-story private ward.

#### MICHIGAN.

**Epidemics.**—Detroit has an epidemic of mumps, and measles is overspreading Albion.

**Dr. Kinyoun Resigns.**—Surgeon Joseph J. Kinyoun, U. S. Marine-Hospital Service, stationed at Detroit since his transfer from San Francisco, a year ago, has resigned, and will reside in Philadelphia and devote himself to bacteriologic work.

**Founders' Day at Ann Arbor.**—The celebration of the founding of the medical department of the University of Michigan, was held February 23, in Sarah Caswell Angell hall, and addresses were made by Dean Victor C. Vaughan; William A. Evans, president of the Students' Medical Association; Drs. Albert B. Prescott and J. Carl Huber.

**War on Quacks.**—Committees from the Wayne County Medical Society, the Detroit Medical Society and the Homeopathic Practitioners' Society, met March 3 to plan a crusade against the quacks of Detroit, who number about forty. Dr. B. D. Harison, secretary of the State Board of Registration, will co-operate with the joint committees in the work.

**Sloane Sues Society.**—Dr. J. Byron Sloane, on March 1, entered suit against the Detroit Medical Society for damages

for his expulsion from that body because of alleged breaches of the medical code of ethics. Dr. Sloane denies that the charges or alleged offenses constitute a breach of the code and says that his formulas and prescriptions are always on file, and that he has not patented a surgical instrument, but has patented an appliance which he has used for the past two years in the treatment of consumptives and others for throat and lung troubles. His attorney says: "We propose to find out whether or not the real merit of a physician, made known to the public by and through the public press, is derogatory either to the medical profession or the public at large, and whether or not the press of the community is to be muzzled."

#### MINNESOTA.

**Hospital Burned.**—The residence and private hospital of Dr. Elias P. Case, Waterville, has been completely destroyed by fire. The patients were all removed in safety. The loss exceeds \$10,000, partially covered by insurance.

**Street Car Disinfection.**—The St. Paul Health Department is to disinfect all street cars in that city every night. The Health Commissioner of Minneapolis does not consider that there is any necessity of joining with the St. Paul department in this particular prophylactic line.

**Physician Freed.**—Dr. Thomas J. Pierce, Duluth, who several months ago was found guilty of performing a criminal operation, but in whose case the Supreme court ordered a new trial, has had the criminal charge against him dismissed, the complaining witness having disappeared.

**Minneapolis Hospitals Dedicated.**—The Norwegian Lutheran Hospital was dedicated with appropriate ceremonies, February 23, and opened its doors to receive patients on the next day. Dr. Edward Boeckmann is the chief of the medical staff. The hospital has, at present, a capacity of 35.—The new Swedish hospital was dedicated on the same day. This hospital will have cost, when completed and equipped, about \$50,000.

#### MISSOURI.

**New Medical Building.**—The contract for the medical building for the State University of Columbia has been awarded for \$29,500.

**Hospital Saturday and Sunday Association.**—At the annual meeting of this Association of St. Louis it was reported that \$24,945 had been realized at the annual collection.

**The Enno Sander Banquet.**—Dr. Enno Sander, St. Louis, on the eve of his 80th birthday, was tendered a dinner by pharmaceutical friends of St. Louis and Chicago, February 26. Albert E. Ebert, veteran druggist of Chicago, and president and historian of the Chicago Druggists' Association, acted as toast-master.

**Antitoxin Investigation Aftermath.**—The logical results of the antitoxin investigation in St. Louis are now taking place. The city authorities have placed the responsibility upon Dr. Ravold, and his resignation followed immediately. There is no question of Dr. Ravold's ability as a bacteriologist, and it was unfortunate, to say the least, that the conditions in the city laboratory made such errors possible. The city should never have undertaken to make antitoxin without a thorough equipment. The bacteriologist was not an independent officer of the Board of Health, but was rated simply as an employe. Now it is proposed to establish the office of "City Bacteriologist," to which the appointee shall give his whole time. Following the conclusion of the investigating committee's work, suits for damages against the city are being instituted by the relatives of the dead children. One suit for \$20,000 is now pending.

#### NEW YORK.

**Canandaigua to Have Hospital.**—Mrs. F. F. Thompson has agreed to erect a public hospital in Canandaigua to cost \$50,000 and to endow it with \$50,000. Two other persons have pledged \$25,000 each to the endowment fund.

**State Vital Statistics.**—The annual report of the State Commissioner of Health states that during 1901, 139,389 births, 64,680 marriages, and 131,788 deaths were recorded. The death rate was 18 per 1000. The mortality was 7500 in excess of the average of the past five years, but the rate was the same as that of 1900. The infant mortality is unusually low, being 3500 less than in 1900 and 2500 less than the average of the past five years.

**Physicians Exonerated.**—The Commissioner of Public Safety has investigated the report that Drs. Winfield S. Hale and E. Hudson Rider of Albany had refused to attend an in-

digent poor sick call, February 17, at the request of a patrolman and has found that the order was misunderstood by the physicians, who supposed the call was for them to attend a private case, which neither of them cared to accept. Therefore the commissioner has ordered that the said physicians be and they are hereby exonerated from any blame in the matter.

**State Hospitals.**—On February 18 Governor Odell signed the bill abolishing the boards of managers of the state hospitals for the insane. These hospitals are the Manhattan Hospital and the Long Island Hospital, in New York; the Hudson River Hospital, at Poughkeepsie; the Homeopathic Hospital, at Middletown; the Matteawan Hospital, at Matteawan; the Utica Hospital, at Utica; the Willard Hospital, at Ovid; the St. Lawrence Hospital, at Ogdensburg; the Buffalo Hospital, at Buffalo; the Rochester Hospital, at Rochester, and the Gowanda Hospital, at Gowanda. The boards of managers of these institutions will retire April 1 and the State Commission in Lunacy will then assume charge of the hospitals. The Governor will appoint boards of visitation for each of the hospitals.

**Liability of Hospitals.**—A bill introduced in the senate by Mr. Grady declares that no hospital incorporated under the laws of this state, sustained in whole or in part by charitable contributions or endowments, shall be liable for the neglect, carelessness or want of skill, or for the malicious acts of any of its officers, agents or employees, in the management of, or in the care or treatment of any of the patients or inmates of such hospital. Nor shall it be lawful for any such hospital to enter into any agreement whereby liability shall be incurred for such neglect, carelessness, want of skill or malicious acts. This bill is not to be construed as to impair any remedy under existing laws which any person may have against any officer, agent or employe of any such hospital for any wrongful act or omission in the course of his official conduct or employment.

#### Buffalo.

**Check to Tuberculosis.**—The Buffalo Society for the Prevention of Tuberculosis is endeavoring to enlist the co-operation of local clubwomen in its work, and has arranged for a number of addresses to be delivered before various clubs on the subject.

**Nurses as Health Inspectors.**—The health commissioner is considering the advisability of asking the Common Council to empower the four district nurses of the District Nurse Association to act as inspectors for the health department. The nurses ask no pay for exercising such authority.

**For a Quarantine Hospital.**—A bill has been introduced in Albany to allow the city of Buffalo to bond itself for \$50,000 for the purchase of lands to be a site for a new quarantine hospital. The funds are to be at the disposal of the common council and mayor, by whom the site is to be selected.

**Personal.**—Dr. Edward A. Southall, University of Buffalo, 1898, a member of the Board of Health of Manila, P. I., has been appointed a member of the medical examining and licensing board of the Philippine Islands.—Dr. Walter L. Savage has been appointed U. S. Government medical examiner of immigrants at this port.

**Gratwick Laboratory Opened.**—The new Gratwick Laboratory was formally opened, February 22. The staff of the laboratory is composed of Dr. Daniel Lewis of New York City, State Commissioner of Health; Dr. Roswell Park, director; Dr. Harvey R. Gaylord, pathologist in charge; G. H. A. Clowes, Ph.D., chemist; Dr. Herman G. Matzinger, bacteriologist; Dr. Irwin P. Lyon, statistician; John E. White, Ph.B., and George Austin, assistants in chemistry; Miss C. A. McClay, secretary, and Miss Alice G. Owen, assistant in microscopy.

#### New York City.

**Borough Pest Hospitals.**—Health Commissioner Lederle is perfecting a plan to build five new isolation hospitals, one in each of the boroughs of Greater New York.

**German and Seney Hospitals.** Brooklyn, have become members of the Hospital Saturday and Sunday Association and hereafter will share in the distribution of the receipts.

**Diphtheria or Smallpox.**—A Brooklyn physician who diagnosed a case of smallpox as diphtheria and who, when convinced of his error, neglected to inform the health authorities, has been fined \$50.

**Donation for Neurological Ward.**—Mrs. Hannah N. L. Sherman of Lawrence, L. I., has given \$25,000 to the Post-Graduate Hospital and College for the partial endowment of a new ward for women and children afflicted with nervous diseases.

**Hospitals Benefit.**—As a result of the German Charity Ball, January 23, there remains \$10,000 to be distributed among the

hospitals and other charities of the city. The German Hospital receives \$1700; St. Francis Hospital, \$1050; St. Mark's Hospital, \$1050; Policlinic, \$1050, and the West Side Dispensary, \$900.

**German Hospital Legislation.**—A bill introduced in the senate by Mr. Elsberg authorizes the city to exchange lease now held by the German Hospital and Dispensary to a grant of the lands upon which the hospital buildings are erected so as to enable the said hospital to convey the whole or any part of said premises in fee simple absolute or to lease said premises or any part thereof for a term of years, the proceeds of such sale or the income from such lease to be devoted to the maintenance and support of said hospital.

#### OHIO.

**Physician's Residence Burned.**—The house and office of Dr. Samuel G. Herrington at Rawson was burned to the ground, February 21. The loss exceeds \$7000, with about \$3000 insurance.

**Semi-Centennials.**—Two of Starling's alumni, Drs. David W. Henderson of Marysville, and Dr. Lafayette Woodruff of Columbus, celebrated the fiftieth anniversary of their graduation, last month.

**Dr. A. F. Shepard,** assistant superintendent of the Toledo State Hospital, was to-day, February 26, elected superintendent of the Dayton State Hospital. The salary is \$1200 a year, residence and other accommodations, and an additional \$400 as clerk of the board.

**Memorial to Fellow Student.**—The members of the graduating class of Starling Medical College, Columbus, have published a very neat memorial souvenir of their class president, Orville Michael Dyson, whose death occurred Dec. 12, 1901, at Pleasant City, Ohio.

**Condemnatory Resolution.**—The Marion County Medical Society has adopted the following resolution:

It is the consensus of opinion of the Marion County Medical Society and other physicians of the city and county, that Senator Harding misrepresents 99 per cent. of his constituents in this district, and that we condemn it and protest against his action on the "Demuth" bill as reported in the daily press of Feb. 18, 1902.

Further, That he misrepresents all religious denominations, except "Dowietes and Faith Cures."

#### PENNSYLVANIA.

**Dissecting Room Fire.**—A blaze in the dissecting room of the West Penn Medical College, Pittsburgh, February 23, caused damage to the extent of \$1500.

**Jewish Hospital.**—The Hebrew Ladies' Hospital Aid Society of Pittsburgh has purchased a site for \$10,000 on which it proposes to erect a hospital to cost \$50,000; the hospital is to be non-sectarian.

**Workingman's Hospital.**—The president of the United Mine Workers of the Pittsburgh district has received an offer from Mr. Andrew Carnegie of \$50,000 toward the erection of a hospital for workingmen.

#### Philadelphia.

**Dr. Leidy Decorated.**—The French government has honored Dr. Joseph Leidy, Jr., with the insignia of *Officier d'Instruction Publique*, for services rendered during the exposition of 1900, where he represented the United States on the International Jury of Hygiene.

**Deaver Dines Society.**—Dr. John B. Deaver gave an informal dinner to the members of the Surgical Society of the University of Pennsylvania which bears his name, at the Fifth Street Rathskeller, February 14. About 175 were present, and Dr. G. G. Ross acted as master of ceremonies.

**The Righter Case.**—In the medicolegal case of Mrs. Nugent against Dr. Harvey M. Righter (previously reported in THE JOURNAL) the County Medical Society has appropriated \$200 toward the defense of Dr. Righter. Many individual members volunteer to subscribe sufficient to carry the case, if need be, to the court of last resort.

**The W. W. Keen Surgical Society** held its annual banquet, February 26. Dr. Keen sent greetings from abroad, and Dr. J. Chalmers DaCosta was installed as guest of honor. Dr. Hobart Amory Hare responded to the toast "High Ideals in Medicine"; Dr. W. L. Rodman to "Reciprocity Between State Examining Boards." Dr. R. H. M. Dawbarn, New York, previously addressed the society and their friends.

**German Hospital Banquet and Musicales.**—On February 28, a banquet and musicales were given and addresses made by Dr. C. J. Hexamer, the Mayor and others, in celebration of the

40th anniversary of the Ladies' Aid Society of the German Hospital. The society has nearly 900 members, pays yearly \$200 for the maintenance of a free bed in the German Hospital, and is now energetically engaged in raising \$5000 for the establishment of another free bed.

**Rush Hospital.**—At the annual meeting of the Corporation of the Rush Hospital for the Treatment of Consumption and Allied Diseases, trustees were elected, including Drs. James T. Mellor Tyson. The latter was also elected secretary of the trustees. The following medical staff was elected: Consulting physicians, Roland G. Curtin, John H. Musser, James C. Wilson, J. P. C. Griffith; visiting physicians, Thomas J. Mays, S. Solis Cohen, T. Mellor Tyson; otologist, B. Alexander Randall; surgeon, Charles W. Dulles; pathologist, William S. Newcomet; laryngologist, Henry J. Oll; ophthalmologist, Wendell Reber; physicians to the out-patient department, John D. McLean, Charles A. E. Codman.

#### GENERAL.

**Savannah Marine Hospital.**—The Senate Commerce Committee has reported favorably on Senator Clay's bill appropriating \$100,000 for the purchase of a site and the erection of a marine-hospital at Savannah.

**Manila Prepared for Plague.**—The Health Department of Manila, P. I., is making comprehensive and commendable preparations to resist a possible outbreak of plague. Five to six hundred rats are captured daily, while numerous others are poisoned. Tents and ambulances are ready in the hands of the sanitary inspectors.

**Colorado Not Averse to Consumptives.**—Owing to the fact that repeated statements have been made that Colorado was seriously considered quarantining against consumptives, it is deemed but just and fair that the following statement, by past or present officers of the State Board of Health and State Medical Society, be published:

We hereby certify on our honor as professional gentlemen:

1. That so far as we are aware, no member of the Colorado State Board of Health ever proposed the subject of preventing tuberculous persons from entering the state.

2. That so far as we are aware, no member of the legislative or executive branch of the State of Colorado ever suggested such a course.

3. That there is no law to that effect on the statute books of the State of Colorado, nor so far as we know has any such law ever been suggested by any responsible citizen of the state.

4. That so far as can be ascertained, there does not now exist, nor has there ever existed, any ordinance to that effect in any city or town in Colorado, nor has there been any suggestion by those in authority, or by any responsible citizen that such an ordinance be passed.

5. That so far as we can learn, there does not now exist, nor has there ever existed, any regulation of any board of health in the State of Colorado covering the subject of quarantining against consumptives, nor has any such regulation been suggested by any responsible citizen of the state.

6. That on the contrary, in February, 1900, the Colorado State Board of Health issued a circular containing the following: "That this climate has saved the lives of many who have come early can not be doubted. There is no need to talk of quarantining against consumption. Such a course is both unnecessary and impracticable. Doubtless, many persons with advanced tuberculosis should not be sent here, but for those who can be benefited by coming, Colorado should have nothing but a warm welcome."

7. That we know of no proposition of the sort mentioned by any one in Colorado, and that all of us who sign this paper have held responsible sanitary positions, and that we have persistently and constantly stated that no such measures are necessary.

[Signed.] Drs. G. E. Tyler, Hubert Work, J. N. Hall, Henry Sewall, L. E. Lemon, Wm. P. Munn, Leonard Freeman, A. A. Clough, and W. H. Campbell.

#### Smallpox.

Philadelphia: There were only 62 new cases of smallpox reported for the week ended March 1, one less than for the preceding week. The health authorities believe that they have the disease under control.

New Jersey: In Camden there are only 25 cases in all, most of which are in the Isolation Hospital. The special vaccine physicians have been discharged. They vaccinated 7000 persons at a cost to the city of \$3500.

Baltimore: Three of the smallpox cases have been discharged cured from the Quarantine Hospital, leaving ten still there.

Ohio: Dr. David H. Miller, Newark, charged with treating a case of smallpox—his wife—in November last, without reporting same to the authorities, was recently tried before a jury in probate court. The secretary of the State Board of Health and the physician employed by the City Board of Health to attend the cases of smallpox in Newark during October, November and December, testified that the patient had smallpox. Two other physicians called to see the patient testified that they believed she had smallpox. Defendant testified that the disease

was not smallpox. The jury agreed in acquitting the defendant.

New York: In the annual report of the Commissioner of Public Health, considerable space is devoted to the prevalence of smallpox during the year. There were 110 places in the state in which one or many cases occurred, there having been during that time 1100 cases with 19 deaths outside of New York City, 1982 cases with 426 deaths in New York City and the maritime district. At the end of the year smallpox existed in sixteen localities, in all of which there was but one case, except at New York and Buffalo, where it was declining in prevalence, at Binghamton and Watertown, where there were several cases, and in lumber camps in the vicinity of Tupper Lake in the Adirondacks, which region, from its exposure to the province of Ontario, from which the cases have come, is the present chief source of concern.

Illinois: The smallpox situation in Chicago affords a refreshing contrast to almost every other part of the country. Only two new cases of the disease were discovered during the week, while 3 were discharged recovered, from the Isolation Hospital, leaving 20 known cases all told in the city. Neither of the new cases had ever been vaccinated; one was contracted from a supposed case of chicken-pox and the origin of the other is as yet unknown. Statistics compiled in the office of the State Board of Health show that since February 1 last smallpox has been reached from 162 localities in 65 counties of the state. Officials of the Board state that the foothold gained by the disease has resulted largely from lack of strict quarantine, some physicians in certain localities where the contagion appeared for the first time terming it chicken-pox, Cuban itch, or Illinois scratches. It is found that where vaccination has been general, few reports of the disease have been received and that where vaccination has been enforced after an outbreak, the spread of the disease has been invariably checked.

Nebraska: The State Board of Health has entered on an educational campaign. It has issued a circular and the "vaccination creed" recently formulated by Dr. Reynolds, of Chicago, is being distributed through the schools of the state.

#### CANADA.

**Obituaries.**—Dr. John Coventry, Windsor, Ont., died on February 22 from pneumonia.—Dr. David Roberge, of Montreal, is dead, aged 32, from pneumonia. He was a graduate of Laval University and for some time after graduation served as house surgeon at the Notre Dame Hospital.

**Provincial Board of Health.**—The new Board of Governors of the College of Physicians and Surgeons of the Province of Quebec has just had elected to membership the following university representatives: University of McGill, Drs. Craik and Lafleur; Laval University, Quebec, Drs. Simard and Catellier; Laval University, Montreal, Drs. E. P. Lachapelle and Demers; University of Bishop's College, Montreal, Drs. F. W. Campbell and J. H. McConnell.

**Undergraduates' Medical Society of McGill.**—This Society was organized in 1879, through the efforts of Professor Osler and Dr. Buller. A fine new reading room has recently been put in order with all the principal medical and scientific journals and the leading daily papers. Its support is assured through the action of the medical faculty since 1886 collecting a dollar from each student as part of his yearly fees. A beautiful tablet has recently been erected by members of the classes of 1901 to 1904 to the memories of two former students: Harold L. Borden, B.A., of Canning, N. S., and A. Patrick O'Reilly, of Hamilton, Ont., who died in active service in South Africa, in 1900.

**Montreal Medico-Chirurgical Society.**—This Society, live and progressive, is entering upon a new era of prosperity. During the past year fine new commodious quarters have been secured in the West End Branch of the Bank of Montreal. They comprise a large meeting hall, nicely and comfortably furnished and capable of seating 125 persons. Adjoining is a coat room and reading room, with a stock room for the accommodation of the library and a committee room. In the reading room all the important medical journals are kept on file. The rooms are in charge of an attendant, and are kept open from 2 to 6 p. m., and from 8 to 11 p. m. The Society will extend its advantages in the future to non-resident members.

**Medical Acts (Extension Bill) and Canadians.**—General Laurie, a member of the Imperial House of Commons, who some years ago was a member of the Canadian House of Commons, has introduced again into the Imperial House his bill bearing the above title. General Laurie was first prompted to introduce this measure on account that "Surgeons of the

highest standing in Canada and holding commissions from His Majesty in the militia volunteered for service in South Africa; but the War Office refused to accept such service on the ground that it was contrary to the Medical Act of 1858 to permit a colonially trained surgeon to attend professionally to British troops." The object of the bill is to remove this disqualification.

**Dominion Registration.**—Dr. Roddick, M.P., has re-introduced his bill into the Dominion House of Commons. The changes in the measure which received the endorsement of the Canadian Medical Association at the last annual meeting at Winnipeg refer particularly to the representation on the proposed Dominion Medical Council which is to be on the basis of population. Dr. Roddick has asked that when the bill receives its second reading it be referred to a special committee of the house, to be composed of all the members who are physicians and two or three prominent lawyers. When the bill is before this special committee delegations of prominent medical men will proceed to Ottawa from all of the provinces of the Dominion; and a determined effort will be made to have the bill ultimately passed through both Houses of Parliament during the present session.

**Bill to Amend the Ontario Medical Act.**—The bill introduced into the Ontario legislature by Dr. Jessop to do away with the homeopathic and college representation on the Ontario Medical Council has aroused the ire of the senate and medical faculty of Toronto University. An elaborate memorandum has been prepared by the Chancellor, Sir William Meredith, and presented to the Minister of Education on the subject. This memorandum takes exception to the bill as follows: 1. It excludes from the body entrusted with fixing and determining the standard of medical education and prescribing the curriculum of studies those who, by reason of their vocation, as well as training, and experience, are, if not best fitted, at least specially qualified for performing those duties. 2. It hands over to a practically irresponsible body the entire and absolute control of medical education, and creates a close corporation or guild. 3. It imposes on the universities and colleges engaged in the work of medical education the obligation of following the curriculum of studies prescribed by the Council without having any voice in the framing of it. 4. It violates the compact entered into with the universities and teaching bodies by which they were given representation on the Council in consideration of their giving up the right to confer degrees or diplomas in medicine and surgery, entitling the possessor of them, without further examination, to practice upon obtaining his license or becoming registered.

#### FOREIGN.

**Prof. Nil Filatow**, the specialist in children's diseases, died at Moscow, February 8, in his 56th year.

**Extermination of Rats.**—The German Imperial Council of Health has appointed a committee to report on measures to be adopted for the extermination of rats as the most dangerous means of conveyance of the plague, especially on ships. Robert Koch is the chairman of the committee.

**The International Congress of Dermatology.**—This congress has been postponed till 1904, to avoid conflicting with the International Medical Congress at Madrid in 1903. Prof. E. Lesser will preside over the congress, which is to be held at Berlin in September, 1904. Dr. O. Rosenthal, Berlin, is the secretary.

#### LONDON LETTER.

##### The Smallpox Epidemic.

The number of cases in hospital on February 15 was 1185, against 870, 1135 and 1102 at the end of the three preceding weeks; 390 new cases were admitted during the week against 204, 499 and 287 in the three preceding weeks. In the House of Commons, Mr. Walter Long, President of the Local Government Board, stated that the number of successful primary vaccinations were as follows: 1898, 500,314; 1899, 669,349; 1901, 677,625. The number of certificates granted to "conscientious objectors" (whereby the penalty for non-vaccination is avoided) were: 1898, 20,341; 1899, 32,345; 1900, 39,839; and for the first half of 1901, 19,252. In the House of Lords, Lord Newton brought in a bill to abolish the "conscientious objector." He pointed out that the legal recognition of this individual had caused 100,000 children to be unvaccinated in the last three years. The bill was defeated in consequence of the opposition of the government, who, while admitting the benefit of vaccination, were unwilling to disturb the compromise of the act of 1898.

#### Casualties in the South African War.

A return has just been issued which shows that the following are the total casualties up to the end of 1901, when the forces amounted to 237,800 men: Killed, 5,231; wounded, 20,937; died of wounds, disease or accidentally killed, 13,733; disbanded and discharged in South Africa, 6,683; in hospital, 11,720.

#### The Investigation of Cancer.

We have previously announced in THE JOURNAL the formation of a scheme for the investigation of cancer which took its origin from the expression of the King, when he received the foreign delegates at the Tuberculosis Congress, of the necessity for checking this dire disease. The following resolution of a special committee was unanimously adopted by the Council of the Royal College of Surgeons on February 13, and at an extraordinary meeting of the Comitia of the Royal College of Physicians on February 18. This committee recommends the two Royal Colleges to consider and develop a scheme for investigation into the causes, prevention and treatment of cancer, and that for this purpose delegates be appointed by the two Royal Colleges (who shall have power to add to their numbers) to draw up a detailed scheme. In pursuance of this resolution the following delegates were appointed to draw up a detailed scheme for systematic investigation into the causes, prevention and treatment of cancer, viz.: As representing the Royal College of Physicians, Sir William Church, Sir William Broadbent, Dr. H. Pye-Smith, Dr. Whipham, Dr. Payne, Dr. Rose Bradford and Dr. Tatham; as representing the Royal College of Surgeons, Mr. H. G. Howse, Mr. J. Langton, Mr. H. Morris, Mr. H. T. Butlin, Mr. Watson Cheyne, and Mr. R. J. Godlee.

#### Ligature of Left Carotid for Aneurysm of the Arch of the Aorta.

At the Royal Medical and Chirurgical Society, Christopher Heath read an important paper on this subject. He reported two cases, which were the sixth and seventh on which he had performed the operation. The sixth case was in a woman, aged 61, who was admitted to hospital in July, 1890, with all the symptoms of aneurysm of the arch of the aorta. She was kept in bed and given large doses of iodid of potassium for many weeks, but no alteration in the pulsation resulted. She always sat up in bed with the knees drawn up and her head resting upon them. On attempting to lean back the dyspnea increased and inspiration became stridulous. The left carotid was tied without an anesthetic, on November 16. On November 19 the respiration was no longer noisy and the patient was able to recline against her pillows. On November 22 she was able to sleep for seven hours consecutively. In January, 1891, there was some return of pain in the right shoulder. In February the pulsating tumor above the sternum had decreased and the patient was able to lie and sleep in any position. She continued to improve. On September 3 the pulsating tumor could be just felt above the clavicle. She died suddenly, November 29. The seventh case was that of a man, aged 36, who was admitted to hospital on Nov. 4, 1898, with aneurysm of the arch. The physical signs were well marked and included tracheal tugging and a blowing systolic sound over the aneurysm. During November, December and January he had severe attacks of pain in the shoulder, back and neck. The aneurysm at first diminished, but in January it increased and definite swelling and pulsation appeared beneath the pectoral below the right clavicle. Mr. Heath tied the left carotid with silk under eucaïn B. on Jan. 18, 1899. On January 20 the pulsation was distinctly less marked and daily improvement followed. On February 6 the patient had pain in his chest and next day his temperature rose to 103 and he rapidly developed symptoms of acute phthisis and died on March 21. The aneurysm gave no trouble and was daily less evident.

Four specimens were shown, one from a man on whom Mr. Heath tied the left carotid in 1872, and who greatly improved for a twelvemonth, when he resumed his hard agricultural labor and the aneurysm began to grow and eventually burst four and a half years after the operation. The second specimen was from a man, aged 38, whose left carotid Mr. Heath had tied on March 8, 1890, and who died suddenly on May 12. The aneurysm was filled with laminated clot. The third specimen, an aneurysm the size of an orange, almost completely filled with laminated clot, was from the sixth case. The fourth specimen was an aneurysm of the arch the size of a clenched fist, with a second small aneurysm of the root of the innominate. Both were nearly filled with laminated clot, the center of the larger being occupied with soft clot. These were from the seventh case. Mr. Heath maintained that ligature of the left carotid undoubtedly produced an immediate effect upon

aneurysm of the arch. He thought that the ultimate solidification of the aneurysm, though its only method of cure, accounted for the sudden deaths which occasionally occurred some months later, owing partly to pressure effects and partly to the induction of syncope.

#### Chronic Edema.

At the Medical Society of London, Dr. Essex Wynter showed two cases of this comparatively unrecognized condition. A single woman, aged 23, enjoyed good health till November, 1900, when she developed a cough which lasted through the winter. For the past ten years she had complained of attacks of misty vision lasting one or two minutes, which had lately increased in frequency. Three years ago there was some swelling of the lips and tongue noticed, chiefly on rising, and lasting two months. Swelling of the face and legs came on gradually and was notably worse since May, 1901, especially after walking or long standing, the legs being at times so stiff she could only flex them with difficulty. In the mornings the swelling was softer and less distinct. The swelling of the face was noticed a few months earlier than in the legs, especially about the right eye. The general health appeared to be unaffected and there had been no pain. The thoracic and abdominal organs appeared to be normal. The urine contained no albumin. Temporary improvement in the swelling of the face and legs occurred under massage. Thyroid extract was given without effect. The second case was a girl, aged 17. About three months ago the face and hands were noticed to be swollen on rising and enlargement of the legs increased. The swelling increased daily and became more persistent. Recently she had noticed some dyspnea on exertion and polyuria. The face was pale and uniformly swollen, the eyes being half closed; the hands also were swollen, but not distorted; and dimples over the knuckles were well marked. The legs were uniformly enlarged and very firm, only pitting slightly on sustained pressure, the skin not being white or shiny. The thoracic and abdominal organs appeared to be normal. The urine was pale, clear, alkaline, of 1009 sp. gr., and free from albumin. While lying in bed there was a marked improvement, but on the patient getting about the measurements of the body returned nearly to their original dimensions, but were not so hard.

#### PARIS LETTER.

##### Operation on the Hindoo Twins by Dr. Doyen.

An operation which has caused much comment in Paris is that which Dr. Doyen has just performed on the Hindoo twins of the Barnum and Bailey circus. Dr. Doyen, whose name is undoubtedly familiar to many American physicians, is the man who rushed across France to Rennes at the time of the Dreyfus affair to take an x-ray photograph of the bullet which had been fired at Labori and had lodged in his back. Professor Reclus was, however, the regular surgeon of the family and refused to have the bullet sought after or extracted. Dr. Doyen is now at loggerheads with another professor, this time the professor of infantile clinical surgery, Dr. Kirmisson. As the Hindoo twins were showing signs of failing health, they were taken to the new Trousseau Hospital, where they were found to be suffering with incipient consumption, and Doodica (the name of the other is Radica) presented symptoms of tubercular peritonitis. Professor Kirmisson was called into consultation by Dr. Guinon, but refused to operate unless he had a written authorization from the foster mother or the agent of Barnum and Bailey. The former would only give it on condition that she could assist at the operation and have it cinematographed. To this Dr. Kirmisson refused to consent, so the foster mother took the twins to Dr. Doyen's clinic, and the operation was carried out on February 9. The operation lasted in all only twenty minutes and Dr. Doyen has given the following account, which is printed in the *Echo de Paris*:

The two sisters were placed on a table covered with a sterilized cloth. I placed myself to the right and cut the skin above the connecting ligament. A certain amount of cartilage was cut through with a lancet. Two little veins alone had to be tied. The peritoneum was then cut and the hepatic band which always exists in such cases was laid bare. There were certain adhesions on the side of Doodica, who, as the diagnosis had shown, was suffering from tubercular peritonitis. The hepatic bridge was 7 centimeters long and 4 centimeters in diameter. It seemed very vascular. This was a case for the employment of the method of hemostasis which I have invented, by the crushing of the hepatic pedicles with my double-lever forceps which gives instantly, under an effort of the hand, a pressure of 2000 kilograms. The hepatic pedicle was superficially fibrous. The crushing was carried out with great prudence, and succeeded so well that two ligatures of catgut *en chaîne* sufficed for Radica. The pedicle, which was very short, was cut between this first ligature and Doodica, and three voluminous arteries were immediately seized with pincers and tied up. The hemostasis, on the side of Doodica, was completed by two ligatures *en chaîne*. The back part of the peritoneum, that on the side of Doodica, and then the skin, were severed with a few cuts of the

scissors. Doodica, liberated from her sister, was carried to a neighboring table, a compress was placed on the wound, and the skin temporarily fastened over it with pincers. The operation was then terminated on Radica, the hemostasis verified, and the abdominal partition was sutured, leaving a morsel of sterilized lint to drain the wound.

The operation itself was cinematographed. This operation has only been carried out once before by Dr. Chapost-Prevost in Brazil. One of the patients died. For the first few days the condition of both Radica and Doodica steadily improved, but on Sunday morning Doodica died suddenly, after having shown symptoms of embolism. Dr. Doyen and the authorities at the Trousseau Hospital have had a dispute in the papers. Dr. Guinon contradicted the statement made by Dr. Doyen that the twins had been worried by medical students examining them, and Dr. Doyen said that when they arrived at his clinic they were found covered with vermin and affected with thrush.

## Correspondence.

### Papers Fraudulently Obtained from the Department of Medicine and Surgery of the University of Michigan.

ANN ARBOR, MICH., Feb. 26, 1902.

To the Editor:—The medical profession may possibly be interested in a brief statement of the following facts: Some years ago I received from a physician at a small town in northern Michigan a letter stating that Dr. Emma W. Mooers, who graduated in the Department of Medicine and Surgery of the University of Michigan in 1884, was practicing medicine in an irregular way in his place. I knew that Dr. Mooers was pathologist to the McLean Hospital at Waverly, Mass., and I wrote my medical friend that the person impersonating Dr. Mooers was a fraud. Papers were issued for her arrest, but before they were served she left the town. Soon after this, the fraudulent Dr. Mooers turned up in Chicago, and I made another attempt to secure her arrest, but again she evaded the officers of the law and for some years disappeared. A few months ago I learned that she had registered under the name of E. W. M. Cory before the State Board of Medical Examiners in Colorado, and I requested Dr. Van Meter, secretary of their board, to secure her arrest. [See THE JOURNAL, March 1, p. 590, Colorado News.] This was done, and the woman was tried, convicted and sentenced to the penitentiary for one year. The judge allowed her to go on parole instead of being sent to the penitentiary, but she is to report once a month, and if she leaves the state she becomes a fugitive convict.

Now, the paper that this woman had was a certificate signed by James H. Wade, secretary of the University of Michigan, stating that Emma W. Mooers had graduated in the Department of Medicine and Surgery of this University in 1884. The fraudulent woman had written to Mr. Wade that she was Emma W. Mooers, who graduated in 1884, and that her diploma had been destroyed by fire, and requested a certificate of graduation. The secretary looked over the list of graduates for that year, and, finding the name in this list, sent the certificate. I report this case because, in the first place, the impersonator has given great annoyance to the real Dr. Mooers, whose work has been of the highest character and whose conduct has always been strictly professional; and in the second place, it shows that university authorities, at least the authorities of this university, have in the past not exercised sufficient care in issuing certificates of graduation to those who have claimed that their diplomas have been destroyed.

Thanks are due to Dr. Van Meter, of the Colorado State Board of Medical Examiners, and to the assisting prosecuting attorney, Mr. Smith, of Denver, for the energy with which they pushed this case. It is possible that the University of Michigan, through its secretary, has issued certificates of graduation to others who do not deserve them, and I desire to call the attention of state boards of medical examiners to this possibility. It is also possible that other institutions have been imposed upon in like manner. Dr. Van Meter, in a letter to me concerning this matter, suggests that it might be desirable for each diploma to contain some description of the person to whom it is granted in order that such a person may be recognized. This is a matter worthy of consideration.

The second instance of obtaining fraudulent papers is quite as serious as the one referred to above, although quite different in character. Last year the medical faculty of this university expelled one of its students on account of gross immorality. He was furnished with a statement of his class standing, and across this statement in red ink was written "Expelled for gross immorality." This statement was signed by the dean and secretary. Some time later, I learned that this man had entered Rush Medical College. I therefore wrote to Dr. Dodson, dean of that school, asking why he had accepted the man. Dr. Dodson sent me the credentials which the young man had presented him. The young man had had printed a duplicate of the statement given him; had made his class standings all right; and had omitted the statement of the cause of his expulsion. More than this, he had forged the names of the dean and secretary of this school. When these facts were made known to Rush Medical faculty, the young man was immediately expelled from that school. Such an experience as this indicates that the officials of medical schools should exercise more care in accepting credentials from other schools. Respectfully yours, VICTOR C. VAUGHAN, M.D.

#### County Society Membership.

KINGSTON-ON-HUDSON, Feb. 24, 1902.

To the Editor:—THE JOURNAL of Feb. 22—page 525—contains a letter from Dr. William P. Munn, of Denver, concerning the reorganization of state medical societies. The point to which he takes exception is that in all cases membership in the county society shall constitute membership in the state society, and that membership in the lower body shall be necessary for membership in the higher. His objection is that this is unfair to certain honorable members of the profession, who are already members of the state societies, but who do not care to work in county organizations. (He also refers to the judicial side of the question, upon which I have no opinion to offer.) From my own experience with physicians it seems incredible that any honorable physician could wish to do other than work in his own county society and do all in his power to make it an organization that would merit the respect of the community, so that when its members came together and expressed themselves in matters pertaining to the public good their opinion would be respected.

It certainly would seem to be just to both old and new members that there should be a common standard for all alike; that the opinion of the majority of the physicians of one's own community, who know him best, rather than that of the members of the state society, should determine one's membership. This seems so just and reasonable that I fail to see any necessity for special exemptions or any good to come from them. When the medical profession of the United States becomes reorganized upon this basis it is reasonable to expect two results: 1. It will wield a power in the national, state, and local affairs worthy of the dignity of the profession; for physicians will have learned how to work effectively together. 2. No physician will be practicing medicine very near, if not over, the border line of quackery, in his own community while still preserving some remnants of professional respectability for himself by membership in a state society, and the American Medical Association. MARY GAGE-DAY, M.D.

#### Reflex in Irritable Urethra.

BAGLEY, IOWA, March 4, 1902.

To the Editor:—An aid in the diagnosis of irritable or irritated urethral mucous membrane and in the so-called uricacidemias, especially in those where there is great benefit derived from a few passages of the cold steel sound, is what may be called the "umbilico-urethral reflex." The elicitation of this is an easy matter in lean individuals, but in fat persons, difficult, yet practicable.

The manner of performance is a movement from above downward of the nail of the forefinger over the exact center of the umbilicus—"a scratching"—and done not quickly or lightly. This causes the above characterized patients to complain of a sharp, shooting, cutting pain, sometimes of momentary per-

sistence followed by a desire to urinate—from the neck of the bladder to the meatus urethric.

I will not attempt to explain the observation, but believe it due to the complex innervation of the fetal remnants of the allantois—the urachus—in the adult, and the genito-urinary tract. I have seen no mention of this in literature to which I have access, but if otherwise I would like to know.

Yours sincerely,

JAS. H. MORROWAY, JR.

### New Instrument.

#### STERILE SOAP MACHINE.

J. H. FIRESTONE, M.D.

FREEMONT, ILL.

The accompanying cut shows something new in the line of a foot-power sterile soap machine for use in operating rooms.

It consists of a cylinder and plunger, operated by foot power, applied to a ratchet wheel acting upon the arm of the piston by a double-thread screw, which forces the plunger into the cylinder. There are two blank screw caps that go with each cylinder. The plunger, cylinder and contents are sterilized before using.

The machine is taken from the bracket and the plunger removed from the cylinder; then the cylinder is filled with green soap and the blank caps are screwed on either end. The filled cylinder and plunger are then sterilized. After sterilizing the blank caps are taken off, the plunger is adjusted and the machine is placed in the bracket ready to operate.

The machine is made in three sizes, each containing ½, 1 or 2 pounds of green soap.

### State Boards of Registration.

Utah State Examination.—The Board of Medical Examiners of the State of Utah held its regular quarterly examination at Salt Lake City, January 6 and 7. The number of subjects examined in were 10; total number of questions, 70; percentage required to pass, 75. The number of applicants were 6, of whom 5 passed.

Can Not Practice in District of Washington Pending Examination.—In the case of a physician of Alexandria, Va., a graduate of the Columbian University School of Medicine, who requests the privilege of following his profession in the District until an opportunity is given him to take the examination prescribed for practicing physicians, Dr. William C. Woodward, the health officer, has submitted a report in which

he says that the licensing of physicians is regulated by the act of congress of June 3, 1896; this law authorizes the issuance of licenses to licentiates of states under certain conditions, but only when such states issue licenses to licentiates of the District under the same conditions; that the State of Virginia does not so issue licenses and therefore that physicians from Virginia are not entitled to the license under the law. The law referred to does not authorize the issuance of temporary licenses pending examination.

### Married.

WILFRED TAYLOR, M.D., to Miss Helen Marot, both of Dayton, Ohio, January 1.

ALFRED J. ABBOTT, M.D., to Miss Jennie M. Congdon, both of Albion, Mich., February 19.

GARDNER PERRY POND, M.D., to Miss Phoebe Painter, both of San Francisco, Cal., February 13.

EMIL MAISNER, M.D., to Miss Sophie Bloch, both of Union Hill, Hoboken, N. J., February 12.

JOHN GRANT WILKINS, M.D., Atlanta, Ga., to Miss Daisy Hester, of Albany, Ga., February 19.

CYRUS D. LLOYD, M.D., Boston, Mass., surgeon of the 44th U. S. Volunteer Infantry, who has served in the Philippines for three years and is now on his way to this country, was married to Miss Mary E. Hiatt, of Leavenworth, Kan., May 23, 1899, in Jackson County, Mo.

### Deaths and Obituaries.

John Coventry, M.D. University of the Victoria College, Cobourg, Ont., 1866, health officer of Windsor, Ont., and one of the prominent physicians and citizens of that place; member and some-time president of the Ontario Physicians' and Surgeons' Association; a veteran of the Civil war, in which while still a student he served on the medical staff of the 16th N. Y. Volunteer Infantry, died at his home in Windsor, February 22, from pneumonia, aged 64.

Louis Lewis, M.R.C.S. England, 1862, Fellow of the Royal College of Surgeons, member of the British Chemical Association, some-time editor of the *Medical World*, *Medical Council* and *Medical Times and Register*, at one time a surgeon in the Royal Army Medical Corps, and for nearly twenty years a practitioner of Philadelphia, died at St. Vincent's Hospital, New York, after a surgical operation, February 19, aged 63.

Henning H. Murrey, M.D. University of Nashville, Tenn., 1898, an esteemed young physician of Nashville and assistant to the chair of surgery in his alma mater, died from meningitis, February 20, after a brief illness, aged 25. The Nashville Academy of Medicine at a special meeting, February 21, passed resolutions of regret and sympathy regarding his death.

James M. Taylor, M.D. Jefferson Medical College, Philadelphia, 1848, who practiced for many years in Indiana, and Kittanning, Pa., but who retired from practice in 1874, died at his home in Indiana, Pa., from strangulated hernia, February 21, aged 82.

Edward K. Bacon, M.D. Michigan College of Medicine and Surgery, Detroit, 1895, one of the most esteemed among the younger physicians of Detroit, died at his home in that city from pneumonia, February 20. The Wayne County Medical Society appointed a committee to draft resolutions touching his death.

Sullivan A. Taylor, M.D. McGill University, Montreal, 1870, who had practiced at Gilmanton Iron Works, N. H., for more than a quarter of a century, died at his home in that place, from valvular heart disease, February 24, aged 63.

George Zabriskie Hunter, M.D. New York University, 1872, for many years a surgeon on the Pacific mail steamers, died from rheumatism, with complications, at his home in Glen Ellen, Cal., February 16, aged 54.

Joseph Jones, M.D. Bellevue Hospital Medical College, New York, 1866, a veteran of the Civil war, in which he served as surgeon of an Ohio regiment, died at his home in San Antonio, Texas, February 24.

George W. Seip, M.D. Jefferson Medical College, Philadelphia, 1862, a specialist on the eye and ear, who practiced in

Stroudsburg, Oil City, and finally in Erie, Pa., died at his home in that city, February 21.

Daniel S. Young, M.D. Albany (N. Y.) Medical College, 1855, formerly one of the prominent surgeons of Cincinnati, Ohio, died at the City Hospital in that City, February 19, from bronchitis, aged 78.

William N. Jett, M.D. Jefferson Medical College, Philadelphia, 1849, the oldest physician in King George and Westmoreland counties, Va., died at his home in Port Conway, Va., February 16, aged 76.

John Johnson Heeren, M.D. Rush Medical College, Chicago, 1899, who practiced for a time in Marinette, Wis., but was soon compelled to go to Colorado for his health, died at Orange City, Iowa, February 23.

John A. Moore, M.D. Keokuk Medical College, 1859, who had practiced in Emporia, Kan., since 1860, died at his home in that city from pneumonia, February 14, after an illness of one week, aged 72.

Alice Ewing, M.D. Northwestern University Woman's Medical School, Chicago, 1894, a practitioner of Chicago, died at the home of her sister in Kenosha, Wis., February 26, aged 52.

George Hunn, M.D. University of Louisville, Ky., 1853, a prominent practitioner of Central Kentucky, died from heart disease at his home in Shelby City, Ky., February 25, aged 73.

M. C. Simmons, M.D. Vanderbilt University, Nashville, Tenn., 1889, formerly of Sutter Creek, Cal., died at his home in Grant's Pass, Ore., from pneumonia, after a short illness.

Daniel W. McKittrick, M.D. Starling Medical College, Columbus, Ohio, 1897, died at his home in Columbus, February 21, after an illness of a year, from tuberculosis, aged 33.

Joseph Temm, M.D., a pioneer druggist and physician of St. Louis, Mo., died at the home of his son in that city, February 19, aged 88.

John T. Moore, M.D. Medical College of Alabama, Mobile, 1891, died from pneumonia, at his home in Orrville, Ala., February 21.

William W. Lark, M.D., a pioneer physician of Monroe County, Ill., died at his home in New Hanover, February 21, aged 67.

### Miscellany.

"Thiersched" Skin Flaps in Plastic Surgery.—J Berg describes in the *Nordiskt Med. Arkiv*, xxxiv, i, 3, his brilliant success with a single skin flap, lined inside with Thiersch slices of the epidermis, in operations to close large defects in the bladder, cheek, etc. He has been treating exstrophy of the bladder in this way for eleven years. The thin layer of epidermis protects the skin flap against the action of the urine. Several of his patients seen again after a number of years demonstrated to eye and touch the excellence of the results obtained, in the smooth, soft anterior wall of the bladder. The method has also proved a success in the treatment of hypospadias, but he has been most pleased with the results in five or six cases in which he had occasion to restore the cheek after removal of a neoplasm or for other cause entailing an extensive defect. He always takes the skin flap from the neck and leaves the base wide until the Thiersch grafts have grown into place, after which he cuts it to the proper size. The success depends mainly on allowing ample latitude for the shrinking of the flap and on the care of the flap during the interval while the grafts are healing, before the flap is sutured into place. A week is usually sufficient. A piece of rubber tissue is sutured over the defect in the cheek in the meanwhile. He has also obtained excellent results in rhinoplasties by combining Mangoldt's cartilage transplantation with a Thiersched single flap when the framework of the nose was destroyed. He has recently treated a defect in the trachea by this combined method, but too recently to judge of the results.

Pneumonia and Exposure to Cold.—It is years now since the medical profession gave up the idea that exposure to cold was capable *per se* of giving rise to pneumonia; we know that the disease is due to a specific micro-organism. But the notion that "this is good weather for pneumonia"—meaning cold

weather—still holds almost unquestioned sway among the people. It is said that the President's son, ill with pneumonia, has been in the habit of taking long walks in the country bare-headed, and that in this practice he has been joined by a number of his school-mates. To this exposure of the head to cold some newspaper writers have felt inclined to attribute the pneumonia. No argument is needed to upset this theory: we have only to point to the experience of the pupils of Christ's Hospital, in London, commonly known as the "blue coat school" on account of the garb worn by the boys. The small blue worsted cap which has always formed part of their uniform they seldom wear, having cast it aside soon after the founding of the school, in 1553. They are to be met with in all parts of London at any season of the year and in all sorts of weather, always bare-headed. This practice of theirs has been going on for more than three hundreds years now, furnishing on a large scale experimental evidence against the notion that cold causes pneumonia, for the disease has been no more rife among them than among other school boys.—*N. Y. Med. Jour.*

**Legal Quacks and Medical Quacks.**—The difference in the treatment accorded unprofessional members of the legal profession by the profession as a whole, and the treatment of similar interlopers in the medical profession, or rather the lack of treatment, has been frequently commented upon. A dishonorable or quack lawyer is disbarred, and he can no longer fleece the public under his respectable cloak. But once a physician, always a physician, and the abortionist and quack, known and condemned as he may be, goes his way so long as he is not behind bars. His evil reputation is indeed often his best card. Still the legal profession is not satisfied with the cleansing of its ranks that has been done, which is commendable. The lay press appreciates the deficiencies also, as shown by the following editorial from the *Chicago Record-Herald* of Feb. 20:

The grievance committee of the Chicago Bar Association has inaugurated what it is hoped will be a serious and aggressive crusade against disreputable and unprofessional lawyers. Through a circular sent to members of the Association it asks the co-operation of attorneys in this work of purging the local bar, and offers to investigate complaints of unprofessional conduct if the allegations pertaining to such misconduct are made under oath, as required by law.

The number of unworthy lawyers in Chicago has grown so large that reputable members of the bar have become aroused to the necessity of doing something to remove the stigma that unquestionably rests upon the profession by reason of illegal and immoral practices. There appears to be general agreement among judges and leading members of the bar that a considerable portion of the 3,700 lawyers in Chicago either violate the statutes governing the practice of law or are persistently guilty of unprofessional conduct. Notwithstanding this acknowledgment the disbarments are known to be very few.

With the ethics of the profession the public is not deeply concerned. The lawyer who insults the court by offensive language or brutally browbeats a witness can generally be dealt with by the judge, and, as a rule, he soon invites the contempt of decent practitioners. Even the ignorant lawyer can be tolerated, especially if he have enough honesty to compensate for deficiencies in legal knowledge.

But the scoundrel and the shyster, who resort to illegal and immoral practices to pervert or defeat justice, who openly violate the statute by fomenting strife that culminates in litigation, should be booted swiftly and unceremoniously out of the profession.

For the ignorant lawyer who was admitted to the bar in the days when the requirements were not so high, there may be room for reasonable leniency. But for the rascally marplot who makes a business of promoting litigation, who is willing to use the testimony of a hired or perjured witness as a basis for a suit, there should be no mercy. Kick him out.

If in this arraignment the word "doctor" is substituted for "lawyer" the situation is still correctly described. The results accomplished by the legal quack are so insignificant when compared with those of his medical congener that they seem trivial indeed, and yet how much does the public or the public press concern itself with the latter. Is it that which touches purse strings more than that which assails health, or is it simply that legal quacks use so much less advertising space?

**Consequences of Nearly Total Strumectomy.**—When four-fifths or more of a struma are removed the results depend on whether the portion left continues to retain its vitality or atrophies. In the latter case there is liable to be acute tetany with or without myxedema, sometimes terminating in recovery. In a case described by Lundborg in the *Upsala Lack, Föerhandl.*

for December 21, acute and chronic tetany were observed. Hoffman reports a similar case, in which a four-fifths strumectomy was followed by chronic tetany, myxedema and myotonic reaction of the muscles. Both patients were young and both improved remarkably under thyroid treatment.

**Tetanus from Carious Tooth.**—*El Siglo Medico*, of February 2, describes a case of severe tetanus which developed suddenly in a young man with no apparent portal of entry. The presence of three carious teeth and the patient's habit of picking his teeth with pins, etc., suggested that a cavity in the teeth might be the focus of infection. The physician had them drawn at once and the mouth thoroughly disinfected every morning under chloroform. The case terminated in recovery.

## Societies.

### COMING MEETINGS.

Medical Association of the Missouri Valley, Lincoln, Neb., March 20, 1902.  
American Association of Pathologists and Bacteriologists, Cleveland, O., March 28-29, 1902.  
Medical Association of the District of Columbia, Washington, April 1, 1902.  
Tri-State Medical Society of Iowa, Illinois and Missouri, Chicago, April 3-4, 1902.  
Tennessee State Medical Society, Memphis, April 8, 1902.  
Florida Medical Association, Tampa, April 9, 1902.  
Western Ophthalmological and Oto-Laryngological Association, Chicago, April 10-12, 1902.  
Medical Association of the State of Alabama, Birmingham, April 15, 1902.  
Medical Society of the State of California, San Francisco, April 15-17, 1902.  
Medical Association of Georgia, Savannah, April 16, 1902.  
Mississippi State Medical Association, Jackson, April 16, 1902.  
South Carolina Medical Association, Spartanburg, April 16-17, 1902.  
Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.  
Association of American Physicians, Washington, D. C., April 29-30, 1902.  
American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

**The Memphis (Tenn.) Medical Society** has changed its name to "The Memphis and Shelby County Medical Society," and will be recognized as the Shelby County Society.

**Medical Society of the Missouri Valley.**—This Society will hold its 14th semi-annual meeting at Lincoln, Neb., March 20, under the presidency of Dr. Richard C. Moore, Omaha.

**Harrison County (Tex.) Medical Society.**—On February 4 it was decided by this Society to endeavor to affiliate with the State Society and delegates were appointed to the May meeting.

**Hancock County (Ohio) Medical Society.**—This Society met at Findlay, February 13, and elected Dr. Myron J. Ewing, president; Dr. Norman L. McLachlan, vice-president, and Dr. Don C. Hughes, secretary and treasurer, all of Findlay.

**Lynn (Mass.) Medical Fraternity.**—On February 9, the Fraternity held a meeting and discussed smallpox and vaccination. Dr. Charles A. Lovejoy, president; Dr. Leonard V. Hatch, vice-president, and Dr. Charles D. S. Lovell, secretary and treasurer.

**New York Academy of Medicine.**—In the Section on Medicine, Dr. James K. Crook has been elected chairman, and Dr. E. Ellsworth Smith, secretary. In the Section on Obstetrics and Gynecology, Dr. James N. West has been elected chairman, and Dr. Louis J. Ladinski, secretary.

**King County (Wash.) Medical Society.**—At the postponed annual meeting of this Society, held at Seattle, February 17, Dr. David A. Mitchell was elected president; Dr. George H. Randell, vice-president; Dr. Guy S. Peterkin, secretary, and Dr. W. T. Miles, treasurer, all of Seattle.

**Southwestern Iowa Medical Association.**—The annual meeting of this Association was held at Creston, February 20. Dr. Enos Mitchell, Weldon, was elected president; Dr. Ross H. Gregory, Nevinville, vice-president; Dr. Joseph P. Claybaugh, Creston, treasurer, and Dr. Frank E. Sampson, Creston, secretary. The midsummer meeting will be held at Albia, August 21.

**Medical and Chirurgical Society of Richmond (Va.).**—The colored medical men of Richmond and vicinity organized this Society, February 19, with the following officers: Dr. Richard F. Tancil, president; Dr. Henry L. Harris, vice-president; Dr. John Meriweather, treasurer, and Dr. O. B. H. Bowser, secretary, all of Richmond. The membership includes colored practitioners of medicine, dentistry and pharmacy.

**New Castle County (Del.) Medical Society.**—The regular physicians of the county met at Wilmington, February 20, and organized a medical society with the following officers: Dr. Willard Springer, Wilmington, president; Dr. Harry G. M. Kollock, Newark, vice-president; Dr. Joseph W. Bastian, Wilmington, secretary, and Dr. James A. Draper, Jr., Wilmington, treasurer. The Society will meet in Wilmington monthly.

**Shelby County (Tenn.) Medical Society.**—The permanent organization of this Society was held at Memphis, February 17. A constitution and by-laws were adopted and the following officers elected: Dr. Joseph H. Stolper, Memphis, president; Dr. Benjamin L. Branch, Collierville, vice-president; Dr. George E. Pettey, Memphis, secretary; Dr. Joseph H. Liebkemann, Memphis, treasurer, and Dr. John H. McKay, Memphis, reporter.

**Pottawatomie County (Okla.) Medical Society.**—This Society was organized at Shawnee, January 27, auxiliary to the Oklahoma Medical Society. The following officers were elected: Dr. J. W. Kerr, president; Dr. A. T. Grayson, vice-president; Dr. Ed. E. Rice, secretary, and Dr. G. R. Connally, treasurer. At the next meeting, February 11, a constitution and by-laws were adopted and the Society started on routine work.

**Grand Rapids (Mich.) Academy of Medicine.**—The annual meeting and banquet of the Academy were held at the Morton House, February 18. Dr. Henry Hulst was elected president; Dr. John R. Rogers, secretary; Dr. John A. McColl, vice-president, and Dr. Earl Bigham, treasurer. Dr. Reuben Peterson, Ann Arbor, spoke on "Maternal Impressions"; Dr. George Dock, Ann Arbor, delivered an address on "Specialism in Medicine," and Dr. Donald MacLean, Detroit, discussed "Professional Plagiarism."

**Eastern Hampden (Mass.) Medical Association.**—At the annual meeting of this body, held at Springfield, February 20, Dr. Walter R. Weiser, Springfield, the retiring president, gave an address on the history of medicine, and prophesied as to its future. The following officers were elected: Dr. George W. Rawson, Amherst, president; Dr. Richard E. Dickson, Granby, vice-president; Dr. George H. Finch, Springfield, secretary and treasurer, and Dr. Harry C. Martin, censor. It was decided to hold the next annual meeting at the same place.

## CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL SOCIETY.

*Regular Meeting, held Jan. 21, 1902.*

The President, Dr. W. E. Casselberry, in the Chair.

DR. OTTO T. FREER read a paper on "The Correction of Deflections of the Nasal Septum, with a Minimum of Traumatism." This article is published in full on page 636 of this issue.

### DISCUSSION.

DR. MOREAU R. BROWN, in opening the discussion, said that, as to the method advocated by Dr. Freer, the length of time the operation requires would cause one to hesitate performing it, and as it is the popular idea, not only among the laity in general but among the members of the medical profession, that the septum is the support to the nose and that if we remove the support the nose is apt to fall in, one should hesitate in removing it. Should the nose become depressed later on through disease or accident and legal proceedings be brought against us, it would be difficult to protect ourselves from the charge that removal of the septum was the cause of the depression of the nose. However, the operation of Dr. Freer is an interesting one and surely would be followed with excellent results in certain cases, though as satisfactory results can be obtained with less disturbance by converting all cases of deflected septum with thickening or outgrowth of the partition into those of simple deflection and then rectifying the latter, as, for example, where the lower part of the septum is dislocated from the septal crest of the superior maxillary or in cases of angular deflection where the septum is thickened; the mucous membrane should be divided and dissected back the entire length of the ridge, the ridge removed and the mucous membrane stitched back in position. The parts heal rapidly within a few days, after which the Roe instruments should be used, first to divide the mucous membrane and the cartilage on the concave side of the septum, secondly by means of forceps to straighten the septum. However, with this precaution, that the smaller size

male blade should be used and not that which was originally intended to be employed with the given size female blade. After the septum has been straightened by this method, the Wyeth's hard rubber tubes are placed in the nose for several days. I have performed this operation without a general anesthetic and have had uniformly very satisfactory results and no complications of any kind.

DR. A. M. CORWIN—With regard to the use of the Roe instruments, especially the Roe forceps, I have had rather pleasing results in using it in the way Dr. Brown has referred to, that is, by employing a small male blade and large female blade. It seems to facilitate the work by giving room for the septum to pass between the blades when they are closed, so that the fracture is more complete. Simple deflection of the septum without thickening affecting the anterior half of the cartilaginous septum, coming away out to the front is very trying to deal with. These septa are frequently extremely thin and bend easily; the whole nose is very flexible. To straighten them properly or to give any result with reference to the relief of stenosis, without great danger of leaving perforation, has been to me at times no small problem. But with the forceps referred to, I obtained a very fair result in one case a number of years ago, by depressing the curvature at the part of greatest convexity—thus converting the simple into a double Cupid's bow-shaped bend and leaving a fair opening on both sides without disturbing the external contour of the nose. In another case I recall I converted a simple bow-shaped into an S-shaped curvature; the patient breathed through the upper curve of the S on one side, and through the other at the lower side. This was a short distance back, from the extreme anterior end of the septum, so that in that case there was a good practical, but not an ideal, result.

DR. E. FLETCHER INGALLS—We find numerous deformities in the nasal septum, and as different physicians have to operate on them they necessarily call for many variations in the operations recommended, and I think for their correction. Some cases are suitable for one and some for another operation, and I presume all of the operations that have gained popularity are adapted to certain cases. The old operation of Chai-sagnac, for example, in which the mucous membrane was dissected up and the cartilaginous tissue pared off, the membrane undoubtedly being replaced, is an excellent one for certain deformities. The Roberts operation, highly extolled for some time, consisted of first cutting through the lower part of the deflected portion of the septum, which was then bent over and a pin thrust in from the free side, through the cartilage and imbedded in the mucous membrane back of the cut on the operated side to hold it in position; another pin was then inserted through the nose to support the first. There appears to have been a good deal of discomfort from this procedure that would not arise from ordinary operations, and few laryngologists employ the method. The Gleason operation consists of cutting out at the bottom and sides a U-shaped piece from the septum. This flap, consisting of the whole thickness of the septum, is then forced through the opening and caught and held by a spur at the lower part of the wound on the other side; this operation is well adapted to some deflections, but is not suitable for those cases in which there is much of an exostosis. The so-called Asch operation is a very good one for a bow-like deflection of the cartilaginous septum, where the bony tissues are not much involved; but when the bony tissues are involved, the criticism by the author of this evening's paper appears to me quite just. There is nothing new about the so-called Asch operation, excepting the instruments that Dr. Asch devised with which to perform it. The crucial incision that he recommended, one incision from above downward and the other from before backward, has been the common practice of general surgeons for ages. In the cases for which this operation is specially adapted the crucial incision can be made better by means of a knife than by Asch's scissors, for with the knife they may be made obliquely so that the cut edges will easily slide by each other, and the abrupt edge made by the edge of the right angle cut will be avoided.

The procedure that has been spoken of as my operation is

designed for those cases in which the cartilaginous septum is bent so as to more or less close the nostril by a nearly transverse triangular plate, narrow above but from 5 to 10 mm. in width at the lower part. The operation consists of removing a triangular piece of cartilage from the front wall of this conical projection of just sufficient size so that the opening will be closed when the lateral wall of the conical projection is brought to a vertical position, but this can not be done without cutting away the lower wall or what from the front constitutes the base of the triangle. This, it should be remembered, runs upward and backward as a hard, bony ridge 2 or 3 cm. It may be cut away with a saw or trephine, but I commonly use the latter. The first incision is made from above downward and outward nearly through the middle of the triangle; the mucous membrane is reflected on both sides of this incision to uncover as large a portion of the cartilage as it is desirable to remove; the cartilage is then cut through, preferably with Sajous' knife from above downward on both sides of the triangle, care being taken not to cut through the mucous membrane on the opposite side. This piece of cartilage is then seized at its apex by forceps and drawn down, the mucous membrane being loosened from its posterior surface at the same time, and cut off at the base of the triangle. The lower wall or floor of the conical projection is next cut away with a trephine, and the resiliency of the septum is overcome by cutting through it beneath the mucous membrane with my small hook-like cartilage knife, or by cutting through it in many places with the blades of my septum forceps. The lateral wall is then pressed over to the normal plane of the septum and held in position by a tampon of surgeons' lint that is made to fill the formerly obstructed naris. This tampon is made from a strip of lint about a centimeter wide and a meter in length, that has been thoroughly impregnated with iodoform and boric acid. The flap is held in position and the outer part of the naris retracted with my bent steel nasal spatula and the strip of lint is pushed in, fold after fold, with my bent nasal scissors which take the place, for this purpose, of forceps and probe, and which by the way add enormously to the facility in packing this cavity. In destroying the resiliency of the septum, I sometimes cut it through at the upper part with a small trephine beneath the mucous membrane, being careful not to cut the latter, at least on both sides at the same time, but several years ago in one case I had sloughing of the flap from such an operation on account of having destroyed the blood supply. This was a very bad case in which the external wall of the projection had pressed firmly upward and outward upon the roof and external wall of the nasal cavity and the operation was followed by severe hemorrhage that necessitated tamponing both sides for many days. I think a chisel would be an excellent instrument for cutting through the upper part of this triangle in destroying the resiliency, although I have never used one. The operation I perform where there is a good deal of thickening of the septum and a spur, as there is in most cases, is somewhat different. With a Sajous knife passed first to the farther end of the exostosis I cut through the mucous membrane from behind forward, as nearly as possible along the crest. When the incision reaches the anterior end of the exostosis it is swept forward and upward in front of the bent cartilage to the upper part of the septum. With a spud this flap of membrane is lifted off of the cartilage and upper surface of the exostosis throughout its entire length. Occasionally, we cut entirely through the septum when there is a deep furrow on the opposite side, but I try to avoid this and can succeed when the furrow is not too deep; however, if an opening is made the flap will usually cover it. I cut away the bottom of the spur with a trephine and then starting the saw at the very upper part of the spur where the septum is in the normal plane, I cut straight down to the floor. The exostosis is thus removed. Sometimes I cut downward with a saw about 4/5 of the whole distance and then insert the saw below and saw upward to meet the cut from above, but the bony tissue is so hard at the lower part of the exostosis that it is easier to cut with trephine than with saw. After the exostosis is removed, the mucous membrane that has been lifted up is applied to the cut surfaces and

covers any opening that may have been made unless the opening is very large, thus a perfect result will be obtained in the majority of cases. Of course, we do not want a fenestrum, yet if the perforation is only in the bony section, it is of no consequence; however, if close to the front, it is sometimes an awkward thing, causing the patient much annoyance from scabbing, and, as Dr. Corwin suggested, sometimes causing whistling, which is not pleasant. I recall one patient who had a very pronounced whistling that kept him awake at night and annoyed all his friends, and I had a good deal of difficulty in closing the opening, though I finally succeeded. I have never tried the operation of taking out all the cartilage advocated by Dr. Freer; it does not seem to me that I should like it. The front portion of the cartilage and the floor is all that I should take out. The external wall is then bent down so as to cover the opening if one has been made and we have a normal septum instead of a septum with only mucous membrane making up the two sides.

The author employs powdered cocaine as an anesthetic. I used it some years ago, but I was not as fortunate as he has been in absence of unpleasant consequences. I had several patients who became very much intoxicated with the cocaine, so much so as to be alarming, and I therefore discontinued using it in powdered form. For several years I have employed a 4 per cent. mixture, which very rarely causes constitutional symptoms; indeed, since using this I have not seen a case of cocaine poisoning that has caused me any anxiety. This solution which I apply with a swab is guarded by atropin 1/10 grain, strophanthus 1/5 grain, ol. earyophilli 3 minims, and carbolic acid 10 grains to the ounce. The carbolic acid appears to prevent absorption into the blood current to the extent that would occur if it were not used.

DR. CHARLES M. ROBERTSON—It seems to me that of all the cases, practically, that come under the care of the rhinologist, there is a redundancy of tissue at the convex apex of the deflection. According to my experience, the matter in most cases resolves itself into simply cutting away the tissue that is hypertrophied at the apex of the deflection. We can save producing a perforation at the point of greatest concavity by a method mentioned, in the work of Shurly, where a saline solution is injected under the mucous membrane at the point of greatest concavity, which has the effect of lifting the membrane up at this point and, therefore, the saw if it should cut through the cartilage does not cut the mucous membrane. I should think in the class of deflections described by Dr. Freer, his operation would be unique; at the same time, the number of cases to which it is applicable would be exceedingly rare, as exostosis is the rule in all cases of deflected septa. I should feel very chary about using powdered cocaine. I have always taught students that it was dangerous to apply cocaine, other than on very small pledgets of cotton on a probe, and then only to the part to be operated on, never allowing the pledget to remain upon the tissues for any length of time. I have seen instructors pack pieces of saturated cotton into the nasal cavity and allow it to remain upon the mucous membrane for ten minutes or more. It has been my unfortunate experience to have seen several cases of cocaine poisoning, even where small amounts of the drug were used and some of them gave evidence of alarming symptoms. I have, by the use of atropin, overcome to some extent the toxic effect of cocaine, and it has been my custom in these cases to place the patient upon full doses of strychnia several days prior to the operation with the administration of stimulants during the operation.

I have never used the Kyle tube, but have used all the rest of them, and to my idea it is about the poorest method of holding the septum in place that could be devised. As to the dressing mentioned, I think anyone would have a hard time in putting iodoform gauze into my nose; I do not appreciate the smell of it, and very many people are susceptible to the effects of iodine. I pack the nose with gauze strips of the same size that Dr. Ingham mentioned, with the exception that I use plain sterilized gauze saturated with sterilized vaseline. The first dressing is allowed to remain in place usually for thirty-six hours, and then the nose is dressed daily for three or four days.

The great advantage in this dressing over the dry gauze is that it does not stick to the tissues, and it keeps the tissues covered with sterilized vaseline, thus affording comfort to the patient, and an ideal dressing to the wound. I have seen elevation of temperature in cases where the gauze was allowed to remain in the nose longer than thirty-six hours, and where there is purulent discharge from the nostril at the time of the operation it should be changed much oftener. I pack the nose thoroughly as far back as I can, doubling the gauze so that it can not project into the nasopharynx, and tight enough to control hemorrhage, and hold the parts in place. The other nostril is left open for breathing. I am not so conservative of the mucous membrane as are some of you, as I have often removed it with the spur under it, and, as yet, have never been troubled with scab formation.

DR. HENRY GRADLE—I have come more and more to avoid the Asch operation, although I have never seen bad results from it. I have always considered the Asch operation applicable only to those cases where we deal with a curved septum without thickening, and with plenty of room on the concave side. This condition is not very common, but it does occur, and in such cases the Asch operation is indeed very useful. When the cut edges overlap too much I trim them at the time so as to get a smooth a septal surface as possible after the regular Asch operation. I have never fractured the bone, only the cartilage. I can also say I have not found it necessary to go back into the bone in the operation Dr. Freer describes in my limited experience with it. I have done it according to the original description of Krieg and Boenninghaus, and not with the refined technique and instruments which Dr. Freer employs. I have not been able to save all of the mucous membrane, but I try to save as much as possible of it. The greatest difficulty I find in the operation is to sever the mucous membrane on the convex as well as on the concave sides, and wherever the bend is angular. When the bend is bow-shaped, the separation is not so difficult. I have used submucous injections of salt solution with some cocaine on the concave side, and found them of some advantage, but not much. In none of my operations did I go back into the bone. In the majority of cases it is the cartilaginous portion which occludes the nose. However, whenever I can I avoid operations according to the Asch or Krieg methods, if possible, and limit myself to removing all edges and spurs so as to gain space thereby, as these operations are less formidable. After all, the saw is the most ideal instrument, if it is applicable, that is if the spur has not too gradual a slope to permit the successful application of the saw. I wish to call attention to two instruments that are not used quite as much as they deserve, not for the condition which Dr. Freer described, but for the removal of ledges or spurs that extend far back. One is a large trephine; mine has a diameter of 8 mm. It is rather difficult to steady this large trephine. On this account I have had a sheath made consisting of a cylinder into which the trephine fits accurately. The posterior part of this sheath is halved in such a way as to represent only a semi-cylinder instead of a complete tube. The sheath is pushed in so that the open portion hugs the septal crest and the trephine working in the sheath cuts away very accurately the portion hugged by the semi-cylindrical part of the sheath. If necessary, I first use a smaller trephine to weaken the bone and finish with one single sweep with the larger trephine. If the trephine does not remove enough in one application, I reapply the sheath to the edge of the wound and cut off another slice.

Outside of two cases of acute mania I have never been seriously alarmed. During the last six years I have used cocaine only on pledgets of cotton, wound very tightly around tooth-picks, so that the amount of cocaine is not large. In this manner I have used 20 per cent. solutions in hundreds of operations, and have never seen any unpleasant results therefrom.

DR. FREER, closing the discussion—Dr. Brown has referred to the possibility of damage suits after the operation I advocate, providing the patient accidentally should fracture and deform his nose at some time after the deflection has been corrected. It is possible that this very statement may direct

the attention of a certain doubtful class of lawyers to the matter, but I think that the fact that such an authority as Dr. Brown agrees with me that the septum is not needed as a support to the external nose and that no member of this Society has objected to my statement to that effect, would deprive the legal action mentioned of all basis. My operation would not weaken the septum more than would the usual operations for correction of deflections. For example, if the septum had any supporting function for the external nose, the operation of Gleason would certainly destroy this more than the window-resection operation would, as the U-shaped flap separated by the saw is certainly incapable of supporting anything, and this flap in extreme deflections is intended by Gleason to include the entire septum from the cartilaginous part anteriorly back to near the posterior border of the vomer. This will leave only a small frame of undivided septum left to furnish the supposed supporting function. The fractures and incisions of the Asch operation would act in a similar way. The amount of cartilage or bone removed by the resection operation that I advocate bears but a small proportion to the portion remaining untouched, so that an abundant frame of untouched septal cartilage and bone, and that composed of the thickest portions, remains. This suffices amply to maintain the form of the septum and preserve its elasticity. I think that the resection operation may be regarded as a standard one considering the large number of cases reported by Krieg and Boenninghaus, with my own in addition.

Dr. Brown's preliminary removal of the dislocation of the anterior inferior angle of the quadrangular cartilage is probably better than my mode of its subsequent excision, as when the main operation is done the patient is disappointed if he can not breathe freely at once. With reference to the stellate punch included in the Roe set of instruments I think that Roe himself has largely given this up for the knife used by him to cut through the cartilage. The suggestion to use a smaller male blade with a larger female one I think would add to the efficiency of the Roe forceps.

I seem to have produced the impression that the resection operation is excessively lengthy. I included preparations and dressings in my estimate of time. The actual operating, even in a case of great deformity, usually does not exceed three-quarters to one hour. I do not think that any surgeon can correct an extreme deflection involving the bone extensively in much less than an hour by any method.

Dr. Ingals has emphasized the usual association of deflection with echondroses, exostoses and thickenings. It has been my fortune to meet a number of deflections of even thickness, but I agree that this is not the rule. The resection method is especially fitted to cope with echondroses and exostoses and especially the greatest difficulty, thickenings of the wall of the deflection. These can all be removed bodily during the operation with chisels or cutting forceps from between the two layers of mucosa. I endeavor to limit the use of the trephine as much as possible on account of its tendency to tear the mucosa into shreds. It is even more difficult to preserve the mucous membrane when a saw is used. The chisel I employ more and more as it does no injury beyond its proper field of action. It is what Nicholas Senn calls "the instrument of precision." By making the incisions made by it in the bony septum meet behind at an angle it is possible to cut out nearly all of a bony deflection with a few blows of the mallet. Operations of the Asch or Gleason type are not fitted to cope with the frequent echondroses and exostoses mentioned by Dr. Ingals.

It is the amount of cocaine in grains or parts of a grain absorbed by the patient that involves possible danger to him and not the concentration of the solution. With powdered cocaine an intense local effect is produced while but little cocaine is absorbed. The swab used is moistened before it is dipped in the cocaine powder so that this is applied in the form of a thick syrup which adheres to the part touched with it while cocaine solutions run and diffuse themselves over a larger surface with greater danger of absorption. Atropin, as suggested by Dr. Ingals, would prove a valuable antidote to the depressing effect of cocaine. Dr. Corwin's lucid explanation of the mode

of action of the Roe forceps was pleasing to me, as he explained so clearly the mechanical reasons for their action, in fact I did not understand the manner in which they produced their effect perfectly until I had seen his drawings.

I have never tried the effect of the injection of saline solution underneath the mucous membrane of the concavity, as I should fear lifting this off further than the operation was intended to go, thus endangering the nutrition of the mucosa.

I am glad that Dr. Robertson agrees with me concerning the use of tubes. I think that he misunderstood me in regard to the material used by me in packing the nostril. I do not use iodoform gauze but lint saturated with powdered subnitrate of bismuth. My packings have never become foul nor have I ever had sepsis follow the operation; this may occur, however, and depends largely on the vitality of the patient.

## Therapeutics.

### PRESCRIPTION WRITING, XVI.

(Concluded from page 698.)

#### Metric System—Continued.

In order to facilitate rapid calculation in the use of the metric system, certain rules have been formulated which render the estimation of the dose of each individual ingredient unnecessary and yet insures accuracy in the amount of each given.

When a liquid preparation is prescribed the amount called for should be 2 ounces or a multiple of two, and when capsules are ordered the physician should write for 15, or a multiple of 15. A 2-ounce mixture, one teaspoonful at a dose, contains practically fifteen doses, since a teaspoon holds a fraction more than a dram. The following will serve to illustrate these statements: The amount of each ingredient prescribed in a 2-ounce mixture should contain as many cubic centimeters (or grams if solid) as correspond to a single dose of the ingredient when given in minims (or grains) in the apothecary measure. This may be seen in the following prescription:

|                                  |    |
|----------------------------------|----|
| R. Quininae bisulph. ....        | 2  |
| Tinct. nucis vomicae .....       | 5  |
| Tinct. hyoscyami .....           | 10 |
| Tinct. card. comp. ....          | 15 |
| Tinct. gent. comp. q. s. ad..... | 62 |

M. Sig.: Take one teaspoonful in water before each meal.

In the above it will be observed that by converting these amounts into the apothecary system and calculating in the ordinary way the number of grains or minims of each ingredient given at one dose corresponds approximately to the number of cubic centimeters or grams of each prescribed. Thus, the 2 grams of quinin will represent 2 grains to the teaspoonful; the 5 c.c. of tincture of nux vomica will give 5 minims to the dose and the 10 c.c. of tincture of hyoscyamus, and the 15 c.c. of comp. tincture of cardamom will indicate 10 and 15 minims of the respective tinctures to each dose.

In a 4-ounce mixture, with a teaspoonful at a dose, the amount of each ingredient contained in the mixture as prescribed in cubic centimeters or grams should be double its dose in minims or grains, so that the foregoing prescription would be written as follows:

|                                  |     |
|----------------------------------|-----|
| R. Quininae bisulph. ....        | 4   |
| Tinct. nucis vomicae .....       | 10  |
| Tinct. hyoscyami .....           | 20  |
| Tinct. card. comp. ....          | 30  |
| Tinct. gent. comp. q. s. ad..... | 124 |

M. Sig.: One teaspoonful in water after each meal.

Following the same rule of proportions, if a 4-ounce mixture is ordered with directions to take two teaspoonfuls at a dose, then the amounts should remain the same as when 2 ounces are prescribed with one teaspoonful at a dose; it would remain unchanged when the patient received an 8-ounce mixture, with a tablespoonful at a dose. But, on the other hand, an 8-ounce mixture, with a teaspoonful at a dose, should contain four times the number of cubic centimeters or grams as there are minims or grains desired in each dose.

In writing for capsules, the same proportions must be observed as in the liquid form.

### Cracked Nipples.

The following is suggested by the *Montreal Medical* in treatment of cracked nipples:

R. Gutta pereba ..... gr. xx  
Spts. chloroformi q. s. to dissolve.

M. Sig.: Apply after each nursing; or:

The following formulæ are very frequently employed in healing fissures of the nipples:

R. Tinct. benzoini comp. .... m. xv    1  
Olei olivæ ..... 3ii    7 50  
Lani ..... 3vi    22 50

M. Sig.: Apply after each nursing; or:

R. Ichthyol ..... 3i    3 75  
Ol. eucalypti ..... m. v    30  
Lani ..... 3v    18 75

M. Sig.: Apply locally after nursing and wash before nursing again.

### Throat Symptoms in Scarlatina.

M. G. Price, as noted in *Med. Standard*, recommends caesium in the throat symptoms of scarlatina, especially in granular and relaxed, enfeebled conditions of the pharynx. The following is used by him as a gargle and administered internally:

R. Tinct. capsici ..... 3i    3 75  
Potass. chloratis ..... 3iii    11 25  
Glycerini ..... 3ii    60  
Acidi hydrochlor. dil. .... 3iii    11 25  
Aque q. s. ad ..... 3xii    360

M. Sig.: Use as a gargle four or five times daily.

The following is beneficial as a gargle or spray:

R. Sodii chloridi ..... gr. v    30  
Sodii boratis ..... gr. v    30  
Ol. eucalypti ..... m. 3/50    0036  
Ol. gaultheriæ ..... m. 3/100    0018  
Menthol ..... m. 3/50    0036  
Thymol ..... m. 3/50    0036  
Aque q. s. ad ..... 3iv    120

M. Sig.: Use as a spray.

### Aspirin in Rheumatism.

Coverly, in *Ther. Gaz.*, reports favorably on the use of aspirin in rheumatic affections. This preparation is a salicylic acid derivative, being a combination of acetyl with salicylic acid. It does not irritate the stomach because it is but slightly decomposed there; the alkaline fluids of the intestine, however, liberate the salicylic constituent, which is then taken into the circulation. Aspirin has also been recommended in neuralgias of tabes dorsalis and in the pain of cancer of internal viscera.

### Diabetes in Children.

The following, according to *Le Prog. Médical*, are of service in the treatment of diabetes in children:

R. Aspirini ..... 3ss    1 90  
Glycerini ..... 3vi    22 50  
Aque q. s. ad ..... 3iv    120

M. Sig.: One to four teaspoonfuls in twenty-four hours; or:

R. Strych. sulph. .... gr. 1/140    00046  
Sodii arsenatis ..... gr. 1/70    00093  
Codeinæ ..... gr. 1/7    0093  
Quinina valer. .... gr. 5/7    0465  
Ext. valerian q. s.

M. Ft. pilula No. i. Sig.: One to six such pills, according to age or ease.

### Pruritus.

Dr. M. B. Hartzwell, in *Ther. Gazette*, states that itching is one of the most common and at the same time annoying symptoms of many diseases of the skin. He relates some of the causes, such as coffee, tobacco and drug habits; or jaundice from obstruction, nephritis, diabetes mellitus, etc. He states that internal remedies, however, are less numerous and less useful than local treatment; and that whatever internal remedies are used local remedies can not be well dispensed with. In mild cases of pruritus, inunctions with petrolatum, oleum amygdalæ, or unguentum aque rosæ, will often suffice, or

bathing the parts in water as hot as can well be borne will in a large proportion of the cases prove effective. But no local remedy, according to his statement, is so generally useful as carbolic acid used either in the form of an ointment or a lotion. The following lotion is recommended by him as a splendid application in all forms of itching:

R. Acidi carbolici ..... 3ss    1 90  
Glycerini ..... 3ii    7 50  
Aq. camphoræ q. s. ad ..... 3iv    120

M. Sig.: To be mopped, not rubbed, upon the affected parts every three hours.

In treating small areas of pruritus, such as pruritus ani, he advises the following paste:

R. Acidi carbol. .... gr. x-xv    66-1  
Pulv. amyli ..... 3ii    7 50  
Petrolati ..... 3ss    15

M. Sig.: Apply locally two or three times daily; or:

R. Acidi carbol. .... gr. x    66  
Pulv. camphoræ ..... gr. xv    1  
Pulv. amyli ..... 3ii    7 50  
Petrolati ..... 3ss    15

M. Sig.: To be applied locally when the inflammation is of moderate severity.

He warns against the use of carbolic acid ointment when large areas of skin are involved, suggesting the use of lotions instead.

He regards menthol as next in rank to carbolic acid as an antipruritic. He employs it in many cases of pruritus ani and pruritus vulvæ. He prescribes it in the form of a paste or an ointment, as it is not very soluble in water and alcoholic lotions are irritable. The following is recommended:

R. Menthol ..... gr. viii    50  
Pulv. amyli ..... 3ii    7 50  
Pulv. zinci oxidi, aa ..... 3i    30  
Ung. aq. rosæ ..... 3v    18 75

M. Sig.: Apply locally. The above paste is of use as a soothing and cooling ointment in the dry and less inflammatory varieties of eczema. He also states that the strength of menthol should rarely exceed 10 grains to the ounce.

The pain to the eyes which it causes when applied to the face makes its use there unpleasant. Resorcin, in his opinion, while not so useful in itching, renders good service in the moist forms of eczema when applied as a lotion. Its power to relieve itching is increased considerably by the addition of a half of one per cent. of sodium chlorid as follows:

R. Resorcini ..... gr. xv-3ss    1-2  
Sodii chloridi ..... gr. xv    1  
Glycerini ..... 3ii    7 50  
Liq. calcis q. s. ad ..... 3iv    120

M. Sig.: Apply locally.

He especially recommends thymol in senile pruritus. It may be employed in the form of a lotion in the strength of one-half grain to the ounce, either alone or in the following combination:

R. Thymol ..... gr. viii    50  
Liq. potassæ ..... 3i    30  
Glycerini ..... 3ii    11 25  
Aq. q. s. ad ..... 3viii    480

M. Sig.: To be used locally two or three times a day.

In the itching of lichen planus the following is recommended:

R. Hydrarg. bichloridi ..... gr. ss-v    03-30  
Acidi carbol. .... gr. xx    1 33  
Ung. zinci oxidi ..... 3i    30

M. Sig.: Apply locally.

In the rebellious cases of pruritus ani and pruritus vulvæ, which are the most annoying of all the itching diseases of the skin, he recommends the following:

R. Argenti nitratis ..... gr. x-lx    66-3.75  
Aq. destil. q. s. ad ..... 3i    30

M. Sig.: Apply locally with a camel's hair brush every second day.

He sometimes prefers spirits of nitrous ether or tincture of benzoin compound similarly applied.

## Medicolegal.

**Not an Expert on Effect of Electricity.**—The Court of Civil Appeals of Texas says, in the case of *Wehner vs. Lagerfelt*, that an "expert," as the word imports, is one having had experience. Here a physician of 35 years' practice was called to testify with regard to the effect of a shock of electricity on the human system. He said that he had read the best authorities on the subject, and knew what the authorities said and claimed to be the result of electricity upon the human system. But at the same time he said he was not an expert, and, to be very frank, did not feel qualified to give an opinion; that he did not know what would be the probable result of a shock from electricity, such as was complained of in this case, from actual experience, because he had no experience in treating such cases, though, from reading the best authorities on the subject, he knew what they said about the matter. He testified to everything he knew about the effect of the electric shock upon the child that had received it, and the court holds that there was no error in refusing to permit anything more to be proved by him. It compliments him on his candor, and says that of all others he was best qualified to know whether he was an expert on the subject concerning which his opinion was sought to be given, namely, that a shock to the human system from electricity, such as had been received in this case, would leave no permanent injury or bad results, and that there would be no tissue change on account of the shock. When a witness states he knows nothing about the subject of inquiry, and that he is not qualified to give an opinion, he should not be permitted to express any; for, in order to say something concerning a matter, the witness should know something. While an expert may testify to an opinion of his own derived from books, for one to do so he must be an expert, and have an opinion of his own upon the subject of inquiry. Books of science are not admissible in evidence to prove the opinions contained therein. If they are not, how can one who knows their contents, but has formed no opinion of his own upon the subject under consideration, be allowed to testify to what the books say? The books themselves would be the best evidence, and they are no evidence at all.

**Communications to Physicians About Accidents.**—In the personal injury case of *Griebel vs. the Brooklyn Heights Railroad Company*, the second appellate division of the Supreme Court of New York says that if the law-making power desires to extend the privilege of secrecy to all statements of every kind made by an injured person to his medical attendant, it is very easy to say so in plain and unmistakable language. Up to the present time, however, the New York legislature has refused to go so far as that. It has limited the privilege to information necessary to enable the physician or surgeon to act in the capacity of physician or surgeon; and when, in any case, it is perfectly plain that the information given is not of this character, there is no reason why the courts should be sedulous to create a protection which the legislature has not seen fit to bestow. It is easy, of course, to imagine cases, and any judge who has had much experience in the trial of negligence suits can recall many, where a disclosure by the injured person of the manner in which the accident occurred might well be deemed necessary to the furtherance of proper surgical or medical treatment. These remarks, of course, do not apply to such cases, but only to those cases in which there is absolutely nothing to indicate that the information disclosed by the patient, and sought to be laid before the jury, could have any possible bearing upon the professional conduct or action of the medical man to whom the disclosure was made. Moreover, the court holds that where it is the duty of the house surgeon of a hospital to find out from the patient how the accident occurred in order to comply with the rules of the institution, then the information given by the patient on that subject may be deemed privileged.

**Mistake Furnishing Deadly Drug Gross Negligence.**—The Court of Appeals of Kentucky holds, in the case of *Smith's Administratrix vs. Middleton*, that to put in charge of a drug business one with authority to dispense such poisonous and

dangerous drugs as morphin, where such one gave such a deadly drug to one calling for calomel, placing it in a box labeled, "Calomel,  $\frac{1}{4}$  grain," without notice of the true nature of the drug furnished, was of itself such evidence of that degree of gross negligence that would warrant a jury in finding punitive damages against such wrongdoer. It declares that it can not say that one holding himself out as competent to handle such drugs, and who does so, having rightful access to them, and relied upon by those dealing with him to exercise that high degree of caution and care called for by the peculiarly dangerous nature of this business, can be heard to say that his mistakes by which he furnishes a customer the most deadly of drugs for those comparatively harmless is not, in and of itself, gross negligence, and that of an aggravated form. In a business so hazardous, having to do so directly and frequently with the health and lives of so great a number of people, the highest degree of care and prudence for the safety of those dealing with such dealer is required; and that degree of care exacted of such dealer will be required, also, of each servant intrusted by him with the conduct of his calling. Nor does the court think that it ought to affect the case against the dealer in the least, however careful and attentive the clerk was ordinarily, if on the particular occasion in question he was negligent or grossly negligent.

**Pointing Out Physical Signs of Injuries.**—The second appellate division of the Supreme Court of New York holds that there was no error, in the personal injury case of *Perry vs. the Metropolitan Street Railway Company*, in permitting a physician to exhibit the bared body of the party suing to the jury, and to point out thereon physical signs of the injuries alleged to have been sustained. The reason it gives is that such physical exhibition was necessary to a demonstration of the deformity testified to by the physician, and tended to make the description of the injury more intelligible to the jury. It says further that there is a manifest distinction between an exhibition of a deformed body by way of a more intelligent and satisfactory understanding of the injury (and its effects where the extent and character of the injury are challenged), and the exhibition of a dead and severed part of the body, where the injury is unchallenged, and when the purpose of the show is to prove a matter of minor importance fully capable of proof by evidence which has no tendency to influence or to prejudice the jury.

**Cross-Examination from Medical Authorities.**—In the cross-examination of certain medical experts, in the personal injury case of *Clukey vs. the Seattle Electric Company*, the experts were asked if such authorities did not lay down certain rules, the attorney reading the language of the rule from the author's work. It was contended that this was an infraction of the rule of evidence against the admission of medical authorities. But the Supreme Court of Washington does not think the rule of law was announced to meet the practice of the kind complained of. It says that these questions were propounded upon cross-examination for the purpose of testing the knowledge of the experts. It would have been competent for the attorney to have stated supposititious cases to the experts. He could properly have stated the rule from memory, asking the experts if such an author did not lay down such a rule. It seems there could be no tenable objection to his reading the rule to the experts. In fact, it is a more exact method, and less liable to make a wrong impression on the mind of the juror, than to cross-examine from memory.

1. **Gonorrheal Prostatitis.**—The frequency, symptoms and diagnosis of this condition are discussed by Van der Poel. He insists on the importance of the prophylactic treatment to prevent gonorrheal inflammation reaching the posterior urethra by instituting treatment in the first 24 to 48 hours. He seems to have faith in protargol as a remedy. The prophylaxis, however, is not always effective, and when this occurs irrigations alone are not sufficient, but massage of the organ must be practiced. He believes in digital massage and describes the treatment by cold and heat. The earlier the cases are seen and treated the less the chance for extension to the epididymis. In the lighter form of gonorrheal prostatitis the prognosis is good, but severe parenchymatous inflammations may lead to serious consequences and are apt to be of long duration. When the abscess occurs, the point of rupture or involvement of neighboring tissues determines the danger of the case.

2. **The Alexander Operation.**—Broun describes his method of performing the Alexander operation in such detail that a full abstract can not be given here. He states that he has followed up with care all the 230 cases operated on at the Woman's Hospital up to January, 1900, as also those which have occurred in his own private practice and finds but one in which the uterus has resumed its backward position. He prefers, for the attachment of the ligaments, to use the black-silk ligature, thoroughly boiled and left in the water until used. An important part of the operation is the preservation of the nerve, which is sometimes caught in the cicatrix after it is severed, producing pain. He notices the complication of hernia following operation and thinks it is due to faulty details of operation either at the external or internal abdominal ring.

3. **Intermittent Claudication.**—Dana describes a case and reviews briefly the literature. His summary is given as follows: "There is a group of symptoms characterized by intermittent or temporary attacks of paralysis, usually of one leg, accompanied with pain, parasthesia, stiffness, and vasomotor disturbances, and absence of pulsation of one or both foot arteries. It is chronic in course and may lead to gangrene, or symptoms resembling erythromelalgia or Raymond's disease. It affects oftenest one leg, but may attack both, and may affect the arm. It occurs in middle-aged people of neurotic temperament, is due to, or associated with, exposure, alcoholism, gout, diabetes, excessive use of tobacco, and syphilis. It is due to arterial sclerosis, causing obliteration of the smaller arteries, also to disease such as aneurysm of the large trunks. The trouble has been called painful paralysis, intermittent claudication, intermittent limping, and, perhaps most appropriately, intermittent muscular paralysis, due to arterial sclerosis. The diagnostic points are the absence of the foot pulse and the symptoms above enumerated."

5. **Extra-Uterine Pregnancy.**—From the observation of 20 cases, all of which recovered, and from cases seen in consultation, Elliot favors a conservative method of waiting until reaction from the shock before operating. Hemorrhage after rupture has a tendency to stop and recur, and probably clot and thus prevent further recurrence. Moreover, the blood is not wholly lost to the patient, but is more or less re-absorbed by the peritoneum. It requires the best surgical judgment to know the right moment for operation and it is always safer to wait than to operate in doubtful cases. When the operation

is to be done it should be done quickly and without excessive handling. Elliot usually scoops out enough clotted blood to find the uterus. He then quickly passes a ligature around the uterine end of the affected tube, which sometimes stops active bleeding, and is a useful handle to pull the tube into view. He next passes a ligature around the other end of the tube and removes the tube from between the ligatures. He never tries to wash out the abdominal cavity or to clean out the clots, because the blood in the abdomen is just what the patient needs, while the manipulation required to remove it takes time and produces shock. He usually closes the abdomen without drainage. He reports a case of combined intra- and extra-uterine pregnancy, calling attention to special points of interest in the case.

**6. Ether Anesthesia.**—Hess attributes vomiting in ether anesthesia to the excretion of ether by the mucous membrane of the stomach, where it acts as a gastric irritant, subsequently causing gastritis. He gives the results of some experiments on animals demonstrating this fact. To prevent the irritant effect of ether on the stomach requires simply the dilution of the ether as it is excreted. A glass of water drunk at the commencement of anesthesia serves to hold in solution considerable ether. Limiting the amount of ether used and the strength of the vapor is always an important factor. This will help to prevent excess of secretion of mucus in the larynx and bronchi, which, when swallowed, adds to the gastric irritability.

**8. Bovine and Human Tuberculosis.**—Smith considers the clinical evidence in favor of the inter-transmission of bovine and human tuberculosis to be comparatively weak, that inoculation experiments are not valid as regards the probability of contagion, and that inoculation does not under all circumstances correspond to natural infection. He describes the morphologic differences between bovine and human varieties. His provisional conclusions deduced from the biologic facts of various types of tubercle bacteria are given as follows: 1. There is no evidence to show that bovine tubercle bacilli may indiscriminately infect the human subject. 2. There is some evidence that bovine bacilli have been isolated from human beings, that the successful transfer is uncommon and that it depends on certain conditions which need careful clinical and pathological study. 3. The evidence that such transmission takes place must be based on the isolation of tubercle bacilli having the characters of the bovine variety. The attitude which these conclusions would lead us to assume toward bovine tuberculosis, at least for the present, does not differ appreciably from that now generally maintained. Periodical rigid inspection of dairy-herds, looking toward the elimination of all animals with suspicious disease of the udder or tending toward emaciation, should be maintained. Beyond this sanitarians can not well go, but every effort should be made to encourage publicly by suitable official recognition those who use the tuberculin test in purifying dairy-herds. Bovine tuberculosis is at best an agricultural calamity and its widespread diffusion and frightful ravages should arouse even the most conservative to bring about by individual effort rather than with the help of the public purse the rehabilitation of the dairy-cow. [See also §16 below.]

**9. Tuberculosis.**—Stubbert's article is a plea for a more standard classification of the different stages or conditions of tuberculosis, giving comparative statements from different authorities in regard to the meaning of the terms: pre-bacillary, incipient, moderately advanced, far advanced, improved, arrested, partially cured and cured.

**10. The Prophylactic Screen.**—Wells recommends the use of a screen by the laryngologist in examining tuberculous patients and illustrates his apparatus.

11.—See also §48 below.

**13. Eclampsia.**—Stroganoff's method of treating eclampsia by the administration of oxygen during convulsions, the use of morphia and chloral for their control, cardiac stimulants when the heart action weakens, prompt delivery when convulsions do not yield to treatment, a milk diet and the avoidance of all depressing influences, has been tested in the Boston City Hos-

pital, and Newell reports the results as follows: 1. In postpartum eclampsia the use of morphia and chloral in combination seems to have a distinctly beneficial action in controlling the convulsions. 2. In antepartum eclampsia the treatment is less efficient than in the postpartum form, but the course of the disease seems to be altered for the better in the majority of the cases. 3. Although the treatment has not given as good results in our cases as in those reported by Stroganoff, a further trial is indicated, since our results have not been any worse than under any other method of treatment which has been tried, and further experience may disclose errors in the application of the treatment which may be remedied to good effect. At any rate, a method of treatment which has proved so efficient in the hands of its originator should not be abandoned until it has had a more thorough trial than we have been able to give this one as yet.

**14. Surgery of the Gall-Bladder and Ducts.**—The first part of this article, which appeared in the preceding issue, is largely a critical summary of the literature of the subject. In the present one he mentions points of diagnosis, question of heredity, previous illness, character of pain, fever, percussion, etc. He thinks early operation will be more frequently resorted to as the medical practitioner becomes more familiar with the correct diagnosis of the disease of the biliary passages. The article concludes with a report of eight cases and a bibliography.

**16. Bovine and Human Tuberculosis.**—Adami summarizes his conclusions, in substance, as follows: 1. Bovine tuberculosis is easily conveyed from cattle to cattle. 2. Human tuberculosis is transmissible to cattle. Pure cultures of these bacilli rarely cause infection. Mixtures of tubercle bacilli with other micro-organisms (as in sputum) appear to be more infectious. The difficulty in inducing artificial tuberculosis favors the idea that natural infection of cattle with human tubercle bacilli must be of singularly rare occurrence. 3. Swine appear to be fairly easily infected with both human and bovine tubercle bacilli and when infected with the former these gain an increased virulence for guinea-pigs and rabbits. But while through the use of infected milk these animals become frequently infected from cattle, conditions favoring the reverse process are rare. For practical purposes, this mode of infection may be neglected. 4. If this be so, it should be possible to eradicate bovine tuberculosis in a region in which human tuberculosis continues to be widespread. 5. Human tuberculosis in the majority of cases is conveyed from man to man by inhalation; more rarely it is conveyed through the alimentary tract, still more rarely through the genital tract, through surface wounds, and from the mother to the fetus during intrauterine life. 6. Everything points to the fact that in the main the bacilli causing infection in man are derived from previous cases of the disease in man. 7. By sojourn in the human body and passage from man to man the human tubercle bacilli have acquired properties differing from those acquired by bacilli which have passed through cattle: their shape differs, the rate of growth and the appearance of the growths outside the body are different; their virulence toward the animals of the laboratory is also different. 8. These differences are not, however, sufficiently marked or constant enough to permit us to conclude that we are dealing with distinct species. 9. Bovine tuberculosis can be transmitted to man through wounds or the digestive tract. 10. By passage through cattle the tubercle bacillus gains increased virulence for cattle, rabbits and guinea-pigs, but lessened virulence for man. 11. Save in the very rare cases of wound infection, there is a significant lack of evidence that bovine tubercle bacilli infect adult human beings. 12. Infants and those of early age are liable to be infected by the tubercle bacilli of bovine origin and this through the agency of milk. 13. Even with children a consideration of the great frequency of bovine tuberculosis in certain regions and of the absence of any record of tuberculosis affecting those supplied from a given "milk round," leads to the conclusion that the bovine bacilli have not heightened virulence. 14. The few positive records we possess of direct transmission of tuberculosis from cattle to man through the agency of the milk indi-

cate that infection is brought about only by the employment of milk of cattle which are very extensively diseased, more especially of those suffering from udder disease. 15. Animals showing physical signs of tuberculosis, and, above all, those exhibiting udder tuberculosis, should therefore be condemned and their milk not be used for food. 16. Where there is tuberculosis in a herd, Bang's method should be employed, the animals reacting to tuberculin being separated from the healthy ones; the milk from the reacting animal, for whatever purpose used, should be Pasteurized so as effectively to destroy the tubercle bacilli.

**20. Surgery of the Spine.**—This is the conclusion of an article which reviews the performance of surgery for various conditions, such as tumors, hemorrhage, spina bifida and fractures. The subjects of Pott's disease and tumors are then taken up, and the author finishes with some remarks in regard to spinal anesthesia. While he considers the method still *sub judice* and not unattended with danger, he points out its advantages. No contra-indication to its use in the areas in which it is applicable has as yet developed, save those pertaining to the mental state of the patient and purely esthetic consideration. Of the latter the operator must be the judge and choose between general anesthesia and subarachnoid lumbar puncture, with due regard to the patient's own ideas so as not to interfere with his psychic morale. The whole article is a critical summary of the general facts in regard to surgery of the spine.

**21. Yellow Fever.**—Reed and Carroll, in this supplementary note, review and detail some of their experiments with the blood of yellow fever cases, both in its unheated and partially defibrinated condition, which partially defibrinated blood heated for ten minutes at a temperature of 55 C., and with the dilute serum which had been filtered through a Berkefeld filter. The object was to ascertain, if possible, whether the blood of a yellow fever patient contained specific micro-organisms as minute as are apparently those of the foot and mouth disease of cattle and certain acute infectious diseases. Test experiments with unheated and partially defibrinated blood produced mild attacks of yellow fever. The partially defibrinated and heated blood gave negative results, while filtered and defibrinated serum also produced in two cases unmistakable attacks. In one case the result was negative. They tested the filter by attempting to pass cultures and staphylococci through it and proved that it was incapable of delivering the ordinary bacilli. He thinks this matter of extreme interest and importance as bearing on the theories that yellow fever might be due to a toxin of considerable potency, or that the specific agent of yellow fever is of such minute size as to pass readily through the pores of the Berkefeld filter. Against the view that a toxin is present in the serum filtrate, the innocuousness of heated blood shown in three cases is important. Though certain bacteria are destroyed at this temperature, we know of no bacterial toxin that is rendered inert by such a low degree of heat continued for so short a time. As a further test they observed the effect that would follow the transference to a third individual of the blood drawn from one of the patients whose attack had been caused by the injection of serum filtrate. If the inoculation of that small quantity were followed by an attack of yellow fever in the third individual evidence would point in the strongest way to the presence of a specific agent of the disease in the blood, since we can hardly believe that the toxin that had undergone so great a dilution in the body of the second individual would still be capable of producing the disease. Experiments showed that yellow fever can be thus produced, and taking into account all the facts in the case they therefore hold that the specific agent of yellow fever passes through the filter.

**22. Tuberculosis Infection.**—Hutchinson finds that animals in cattle ranges are not free from tuberculosis and insists on the importance of tuberculin examination of dairy animals and the withdrawal of tuberculous meat and milk from use by human consumers.

**23. Treatment of Insanity.**—The points especially mentioned by McGugan as of importance in the treatment of in-

sanity are rest and exercise, massage in connection with the rest cure, care as to diet, hydrotherapy for sedative, tonic and eliminative purposes, surgery (gynecologic) in suitable cases where abnormality exists, electrotherapy in depressed states, the use of hypnotics and motor depressants in certain cases, sedatives and general tonics. For instance, in a recent case coming to the hospital the first thing is a bath; the patient is put to bed in a quiet room; general and physical examination for diagnostic purposes are made with great care and psychologic analysis carried on over an indefinite period. If this is not sufficient in excited cases, sulfonal, combined with bromid or hyosein, is administered. In the depressed type the prolonged tepid bath is prescribed, followed by a light superficial massage; simple enemas are given every second day for two or three weeks; the static spark is applied to the spine and the crown breeze to the head; rest for the first few days is ordered, followed by gradually increasing the exercise. He says that out of 319 acute cases admitted during three years, 108 were subsequently diagnosed incurable and transferred to the different wards of the asylum. Of all the 211 remaining, 104 were discharged restored, 44 improved, 13 died and 50 still remain under treatment.

**24. Perineal Section in Stricture.**—Lydston maintains that perineal section is often advisable, especially in traumatic strictures even if not extensive, and in those complicated by fistulas or severe cystitis. Deep stricture complicated by retention of the urine should be, as a rule, treated conservatively—that is, temporized with at first—the ultimate treatment being decided later. But in some instances, as in hospital practice and in patients coming from a distance, immediate perineal section is the safest procedure. The same is true where the patient does not have access to skilled attention during the after-care of the case. Impermeable stricture is exceptional, but not so infrequent as some would have us believe and perineal section in such cases without a guide may be necessary. Experience has taught Lydston that under these circumstances where the urethra can not be found in the perineum, except by tedious and extensive dissection, it is far better to make a suprapubic cystotomy and perform retrograde catheterization. The surgeon who has had but little experience with perineal resection, called on to operate in such cases, had far better enter the bladder from above and combine the perineal and suprapubic cystotomy.

**25. Tuberculosis.**—Wright goes over some of the recent points in the literature in regard to tuberculosis, calling attention to the importance of individual resistance and holding that the present state of our knowledge does not warrant isolation or inconvenient regulations affecting patients. The idea of the extirpation of the tubercle bacillus, he thinks, is a little too ideal and he quotes Grawitz to this effect. Other points mentioned are the question of human and bovine tuberculosis with their virulence in different cases, the pleomorphic nature of the germ as shown by Heuppe, and the danger that bacilli resembling the tubercle bacillus will lead to errors in diagnosis. At present there is no room for dogmatic assertions in regard to the condition.

**26. Anesthesia in Throat Surgery.**—From an observation of the various ways of administering nitrous oxid as a preliminary to ether, Maduro concludes that it should be carefully ascertained that the valves of the gas apparatus fit accurately, so that there may be a rapid exit of atmospheric air from the lungs. A certain amount of re-breathing of nitrous oxid should be allowed at the end of its inhalation, in order that a longer gas and a shorter ether anesthesia may be obtained. The transition to ether should be accompanied by a rather free admixture of air through the various inlets in the apparatus without removing its face-piece. Lastly, the head of the patient should be well drawn back, and forward pressure made on the jaws, at the time of the transition to ether, so that the airway may be increased to its utmost. Maduro amplifies on these recommendations, giving reasons for each. The actual time necessary for all the details and until the patient is ready for the operation should average about five minutes. As regards

other anesthetics, he would give chloroform a very limited field. Its tendency to cause laryngeal closure in conditions of obstructed breathing through disease must be given some thought, and the danger of pushing it should be remembered. The same is true to a greater or less extent of mixtures containing chloroform; ethyl chlorid acts disadvantageously in these cases, and ethyl bromid is too evanescent and far from safe.

**31. Cardiac Neuroses.**—Crook's article goes over the nomenclature of cardiac neuroses. Palpitation, tachycardia, neurasthenia cordis, arrhythmia and angina pectoris may be regarded as distinct separate conditions. Bradycardia itself is largely a secondary condition, not, as in tachycardia, the principal symptom group in the disease. Arrhythmia and tremor cordis are really not diseases, but symptoms. He considers it not altogether correct to call Graves' disease a cardiac neurosis. True angina pectoris is always accompanied with organic disease and is no more a neurosis than is atheroma or endocarditis. Pseudo-angina is indisputably a neurosis. The recognition of true angina, he says, should not be difficult. No other condition presents the same complex of symptoms—sudden irradiating pain, squeezing, tightening, constriction, overwhelming fear of immediate death. From pseudo-angina it is distinguished by its occurrence almost invariably in males past the meridian of life and by its greater severity. Huchard's aphorisms, while not infallible, are important: Every angina produced by effort is a true angina; every angina which occurs spontaneously without effort is a false angina; but an angina occurring at night, though independent of effort, is a true angina. The absence of all signs or symptoms of organic disease of the heart creates a presumption in favor of pseudo-angina.

**32. Practical Pharmacy for the Physician.**—The question as to how practitioners are to acquire a practical knowledge of pharmacy can only be answered in general. Hargrave suggests to those who write prescriptions: 1. Study the properties of drugs and preparations used whenever an opportunity occurs. 2. Carefully inspect every prescription written when filled by a competent pharmacist. 3. Study the subject of incompatibility. To those who dispense their own drugs he suggests: 1. Study the subjects of extemporaneous pharmacy and incompatibility in any text-book on pharmacy. 2. Note the appearance, odor, etc., of all drugs and preparations handled, and avoid the indiscriminate mixing of drugs without regard for their properties. 3. Be careful, accurate and neat in every manipulation.

**33. The Poultice Method in Abscess Cavities.**—The method here discussed was first described in the *Atlanta Journal-Record of Medicine* for April, 1900. Hutchins suggests applying over the opening of the abscess a poultice of flaxseed meal, made with 3 per cent. carbolic instead of plain water. A thin cloth or gauze layer can be put next to the opening. The 3 per cent. of carbolic acid really becomes about 1 per cent. in the mixture and is hence very weakly germicidal. Absolutely nothing is put in the abscess cavity; it is simply emptied of pus by pressure—through a small opening—if not already open. The poultices are changed as often as cleanliness or their getting dry requires. The wet poultice affords constant drainage and absorbs the discharge. There is no premature union of the mouth of the cavity, no introduction of foreign substances, no reinfection in dressing and the saving of 75 to 80 per cent. in the time of healing. The small incision may be used instead of the free and long one. He reports a number of cases which he thinks show the superiority of this method over the usual one.

**38. Benzoate of Guaiacol.**—Earp finds this substance one of the best methods of using guaiacol, being comparatively tasteless and odorless, doing away with the annoying eructations and the gastro-intestinal irritation. He uses from 3 to 6 grains dry in capsules, four times a day, with gradual slight increase in dose if deemed advisable. In phthisis he finds four favorable results, partial subsidence of cough, diminished expectoration, enhanced appetite and increase in flesh. In some cases these results were very pronounced. He has also found that certain catarrhal conditions of the intestines and irritable

states of the bladder are sometimes relieved during the administration of this drug.

**48. Prostatic Hypertrophy.**—The subject of prostatic hypertrophy is gone over at some length by Bernays, who sums up his conclusions in the following: 1. In old cases of hypertrophied prostate, palliative measures are sometimes preferable to radical measures. 2. Drainage of the bladder by the suprapubic route is preferable to perineal drainage in cases of cystitis, because the suprapubic method gives the sphincter apparatus more complete rest than the perineal buttonhole or fistula. 3. In cases of hypertrophy in which the patient's health has not been injured by chronic cystitis or nephropylitis, the dangers of myomectomy or perineal prostatectomy are minimal, and in these cases a radical and satisfactory functional result can be achieved by myomectomy. 4. Botini's operation must be regarded as a palliative measure, intended to enable the patient to evacuate his bladder more completely than before. It will probably have a very limited usefulness and will be crowded out of practice as the technique of myomectomy or perineal prostatectomy is perfected. 5. Botini's operation is a dangerous operation and must not be undertaken unless most careful measurements have been made. It is often followed by extravasation of urine into the perineum, and the perineal section must be done in order to save the patient's life as soon as swelling of the perineum is noticed. 6. Myomectomy done through a perineal incision is the operation which promises the best results, and is the operation of choice. It is applicable to the greatest number of cases in which permanent cure may be expected, the kidney being physiologically sufficient and unimpaired. The greatest dangers associated with prostatectomy are produced by injuring or removing parts of the capsule of the organ. Myomectomy must be done without this dangerous manipulation. As long as the capsule is left intact there is but little hemorrhage, and the danger of infiltration of urine and sepsis is reduced to a minimum.

**50. Transmission of Consumption.**—Behrens, reviewing the evidence in regard to the transmission between men and animals, concludes that human sputa are predominant in the transmission of tuberculosis; that hereditary consumption is rare and that predisposition is inherited; that immunity is rendered to off-spring born during the tubercular disease of the parent is far from being proven; that milk, meat, cheese, butter, etc., derived from tuberculous animals, can produce tuberculosis in the human being is his belief. He thinks that more stringent rules regarding expectoration, isolation, hygiene and sanitation should be enforced, and as a result consumption would belong to that class of diseases such as scurvy and smallpox, often heard of but seldom seen.

**58. Myasthenia Gravis.**—Down reports a case in detail and discusses the diagnosis, symptoms and etiology. He finds nothing that can be properly considered a cause. Thus far no satisfactory treatment has been discovered. He advises prolonged rest, nourishing food, attention to the excretions and brief periods of exercise.

**59. Respiration in Tubercular Meningitis.**—The case reported by Eskridge is that of a woman whose respiration varied during her illness from 8 to 138, but usually was rapid. He discusses the hysteric element in the case and its probable organic pathology involving the respiratory centers. He thinks in this case that the subordinate centers of respiration, the cutaneous, optic and auditory nerves, those of the lungs, cord and cerebrum, were practically held in abeyance by the predominating centers of respiration in the medulla, which were directly irritated by a lesion in the medulla. He thinks the influence of the blood on the centers of respiration was overpowered. He says, in conclusion, that in a case of hysteria we may perceive the veil that obscures or the cloak that hides the symptoms of organic disease, or grave disorders of functions in some important organ. Respiration, which is more rapid while the patient is asleep, is strong if not positive evidence of organic disease of the brain in the region of the respiratory centers.

**64. Traumatic Neuroses.**—Nuzum concludes from both clinical and experimental investigations that slight injuries

may produce spinal neuroses, but that sprains are often mistaken for severe injuries and that the majority of cases against great corporations are either feigned or exaggerated. Traumatic hysteria is very intractable to treatment and death may occur without any physical lesions being found either before death or at the postmortem. Injury may be the exciting, not the remote, cause of locomotor ataxia, but epilepsy, apoplexy, and paralysis agitans may be caused directly and wholly by a traumatism. Generally, however, the prognosis is one of ultimate recovery. In traumatic nervous injury the more serious symptoms of organic nervous disease are present. From experiments on rabbits he comes to the following conclusions: 1. Concussion of the spine, causing loss of function for a variable length of time with physical lesion, is readily produced by a blow directly on the back. 2. The degree of concussion depends upon the force of the blow, and may be of momentary duration or last for days or weeks. 3. A blow on the back of the neck may prove immediately fatal without producing any visible injury. 4. It is difficult, if not impossible, to produce concussion of the spine by a blow upon the nates. 5. Rabbits that were subjected to repeated experiments did not show such marked nervous phenomena as they did the first time. 6. The microscope shows a tigrolysis and pyknosis of the tigroid of a considerable number of the ganglion cells of the motor roots, in cases that have suffered from concussion of the spine.

67.—See abstract in *THE JOURNAL*, xxxvii, p. 852.

69.—*Ibid*.

76. **Colloid Degeneration of the Skin.**—White's article is largely a critical review of the literature in regard to this condition, which has been mentioned and described by Unna, and which consists in the breaking down of the fibrous tissue and the combination of collagen and elacin and the further disintegration into the homogenous mass known as colloid. A case is described with microscopic characteristics.

78. **Vaccinia Generalisata.**—After reporting a case, Heidlinsfeld discusses the possible methods of its origin. He disbelieves in the inoculation theory in this case and says that in all probability there are two separate types of eruption in these cases, one due to direct inoculation or misdirected virus, of shorter duration, persisting until vaccine immunity establishes itself, and characterized by lesions of the vaccine pustule; and another the result of systemic intoxication of variable duration, with lesions atypical to the vaccine pustule, both as regards course and appearance. Both require special idiosyncrasy on the part of the patient and have nothing in common with localized complications like erysipelas and eczema.

85. **Parametritis Posterior.**—The affection thus designated by Schultze consists in an inflammatory affection of the rectouterine muscles, springing from the wall of the uterus. Ewald reports cases and discusses the nature of the affection. His conclusions are: 1. The parametritis posterior of Schultze and the paraproctitis of Freund (also called parametritis atrophicans) are one and the same disease, in fact a disorder of the connective tissue and not of the peritoneum. 2. Parametritis posterior is commonly combined with inflammatory processes in the peritoneum and disease of the tube and ovaries. When retroflexion also exists ventrofixation is indicated and is to be preferred to other methods of treatment.

93. **The High Retraction Ring.**—The existence of the high retraction ring as a contra-indication to version is treated of by Holmes, who describes the mechanism, diagnosis and therapeutic considerations. The object of his paper is to call attention to the importance of this condition in the mechanism of abnormal labor and its prohibition of a certain obstetric operation, rather than to go into the minutiae of anatomic details or operative technique. He thinks obstetricians should endeavor to detect this as a routine practice, and as the question of version arises it should be determined before extreme distension of the lower segment begins. Usually the high retraction ring follows the more or less prolonged escape of liquor amnii. With intact membranes at the moment of beginning the version the hazard of rupture is greatly reduced, for the version

may be carried out before the uterus has had time to retract. When in doubt as to the advisability of performing version it is perfectly permissible to prepare for the operation, to pass the hand into the lower segment very cautiously, and if it is thin and the ring high one can with propriety remove the hand and proceed to another method of delivery.

95. **Urethral Reinfection from the Bladder.**—The acute relapses in chronic urethral disease include a peculiar type first noticed by Harrison, which can be proven to be due to reinfection from the bladder. The preliminary symptoms are cystitis following some indiscretion of diet or other cause. The patients are taken suddenly ill, sometimes with a chill, then a fever, and in the course of two or three days a urethral discharge makes its appearance, which is usually never copious, varying somewhat in color and consistency, with typical signs and symptoms of posterior specific urethritis. Cystoscopically we find the trigonum to be the seat of chronic inflammation and the posterior border of the internal urethral orifice is swollen. The epithelial cells are edematous, and in cases usually called urethro-cystitis the entire posterior urethra is similarly affected, but in cases where the urethra has not yet become affected there is a sharp line of demarcation. The practical deductions which he makes from the facts are that every case of apparently cured chronic posterior urethritis, if doubt exists, should be cystoscoped in order to recognize any latent bladder disease. If such is present it should be treated accordingly. If necessary the entire granulating surface of the trigonum can be thoroughly euretted in order to obtain a permanent cure.

106. **Vaginal Fibromyomata.**—From an extended study of the subject with reported cases, Smith summarizes as follows: Fibroma (myoma and fibromyoma) of the vagina is a rare disease. It occurs most frequently in women between 30 and 40, but has been observed at ages ranging from 20 to 70. The cases observed in infants are open to some doubt as to diagnosis. It apparently occurs independently of civil condition. No proof can be deduced to show that it affects fertility. It may obstruct labor when large. When the growth is small it rarely affects coitus, and may not do so even though the growth be large. There is some evidence that in certain cases menstruation may be increased. The tumors, when small, rarely produce symptoms of consequence; when large they may prove to be the source of considerable suffering and even danger. The symptoms, when present, are pain, hemorrhage, discharge, obstruction to bladder and rarely to bowel. No exact division of the case into fibroma, myoma and fibromyoma can as yet be made. The term fibromyoma will probably cover most of them, but pure fibroids have been observed. Pure fibromyomata may also exist. The tumors grow from anterior or posterior wall in proportion of about 2 to 1. They may be sessile or polypous. They vary greatly in size and are usually single. They are, as a rule, very slow of growth and prone to edema, necrosis and ulceration. The treatment is essentially surgical.

107. **Puerperal Fever.**—For a number of years Moran has been making examinations of the relative morbidity of cases examined and not examined internally during the labor with and without rubber gloves. No prophylactic douche was used in either class. Of 317 cases admitted at the Columbia Hospital between July 1, 1899, and Sept. 30, 1900, 180 were examined during and after labor and 138 were not examined. Of those who were examined, 40, or 22 per cent., had a rise of temperature above 100. Of those not examined there were 26, or 19 per cent. A careful clinical and bacteriologic examination revealed in those 40 cases conditions accounting for the temperature, such as sapremia, mastitis and gonorrhea, in a much larger proportion than in those not examined. From Oct. 1, 1900, to May 30, 1901, 237 cases were treated in which rubber gloves were used; 193 cases were examined and 40 not examined. Of those that were examined 43, or 20.7 per cent., had a rise of temperature above 100; of those not examined 7, or 17.5 per cent., had a rise above normal. It appears that the morbidity is dependent on the various general as well as septic infections; that the latter are doubled in number in cases examined over those not examined, and the percentage lower in those cases where gloves were used. He suggests the following

measures during the puerperium: 1. Careful observance of aseptic technique on the part of the physician and nurse, at all times regarding the parturient tract as a surgical wound. 2. Restricting or avoiding internal examinations and cultivating external diagnosis. Where internal examinations are made care should be exercised to separate the labia, so that the examining finger will avoid contact, as far as possible, with the vulva. 3. A thorough knowledge of the mechanism and conduct of labor, with due appreciation of timely interference. 4. Refraining from haste or violence in expulsion of the placenta. 5. Avoiding early rupture of the membranes. Every case of delivery should be regarded as septic until positively excluded by a most careful and painstaking examination.

**112. Non-Surgical Premature Menopause.**—In the case reported by Walter the menses stopped in a young woman, aged 23, after a severe nervous shock. She suffered for a time from bronchitis and cystitis (?). She had severe headache, was very nervous, had characteristic vasomotor disturbances and suffered from hysteric attacks. All efforts to establish the function failed in spite of general and local treatment. She still suffers from certain symptoms, though she has not been ill in bed save for some slight illness for about nineteen years. The most irritating symptoms are frequent urination and suddenly appearing diarrhea. There is now complete atrophy of the uterus, ovaries and tubes. The uterus is only about one inch in length, small and flattened antero-posteriorly. The external organs are only slightly atrophied. The mammary glands are round and full. Her general appearance is that of a woman much younger. Her form is graceful and plump, but not at all stout; general disposition is happy and rather cheerful. She has lost slightly in weight, but has had no symptoms pointing to tuberculosis. The author reviews the literature of similar cases and reports several from it. He says the aim of his paper is to point out that: "1. Premature menopause can occur without any previous or subsequent disease. 2. Premature menopause is not necessarily preceded by any change in generative organs. 3. Any changes found in these organs are probably post-menopausal, or due to disease, not all related to the menopause. 4. Premature as well as normal menopause is due chiefly to atrophy, inhibition, or disease of a local menstrual ganglion and nerve plexus, rather than disease or atrophy of generative organs."

**123. Locomotor Ataxia.**—Mitchell discusses the treatment of this condition and remarks that it is hard to judge whether a certain treatment is doing good or not. In almost all cases, certainly in all in the secondary or moderately ataxic stage, rest is of vital importance. Improvement by re-education of impaired motor faculties is one which he leaves to be taken up at some future time. It should not be begun before at least a month's rest in bed with massage. He emphasizes the immense value of this latter measure which can well take the place of general exercise in the maintenance of health. For gastric crises he believes in stomach lavage, which has relieved cases in his hands. The use of firm bandaging with a flannel roller for tabetic pains in those limbs has given great relief in some cases. He has found faradism as efficient as galvanism for this purpose, and would put it first among the three forms of electricity to be employed in such cases.

**143. True Torticollis.**—There is but one variety of wry-neck, according to Hoffman, in which treatment is directed purely to the deformity and which deserves to be spoken of as a distinct affection. In all others the torticollis is simply an incident. This variety is usually present at birth or soon after, and is due to permanent shortening of the sterno-mastoid muscle and to the other cervical structures accommodating themselves to the malposition. This he calls true torticollis. No theory that has been advanced to explain its occurrence has been directly proven; probably the most plausible are abnormal pressure *in utero* and the arrest of muscle development from obscure, perhaps central, origin. The right side is most frequently involved, according to most observers. There is usually more or less fibrous degeneration in the muscle, but in time the other muscles of the side become shorter and even the cervical vertebrae are distorted by unequal pressure. There are also curvatures of the dorsal and lumbar spine and facial

and cranial asymmetry in nearly every instance. When of slight degree and seen very early daily manual correction by the mother or nurse will suffice. Mechanical appliances are generally disappointing. As regards operation it is manifestly impossible to cut everything that offers resistance to the correction of the deformity; therefore, division of the sterno-mastoid and forcible stretching of the other tissues are resorted to. He favors subcutaneous tenotomy for this condition and gives illustrative cases thus operated upon. He calls attention to the danger of cutting the jugular vein and the possibility of wounding the common carotid artery. After operation the head is fixed in an over-corrected position by plaster dressing and allowed to remain several weeks, and the post-operative treatment continued many weeks or even months. Usually the sterno-mastoid recovers its function and can be converted into a useful organ if the cut end can find a point of attachment. This usually occurs by new material growing into the gap, but he records an observation where the muscle, though retaining its function, had apparently not united with the lower piece, but had become attached by its free end to the fascia higher up, and from which new attachment it exerted a pull upon the head.

Bazzicalupo (Naples).—"La sindrome cerebro-spinale nel saturnismo (paralisi progressiva saturnina)." 2 and 3. Typhoid Fever.—Turner, as medical officer of health of the Transvaal, argues against the air-borne theory of typhoid. He does not deny its possibility, but thinks that it is not usual or even frequent. As regards flies, he holds a similar opinion. He gives his observations to show that the typhoid in South Africa is almost entirely due to polluted water. The filters sent out for the troops, he claims, were not used or quickly got out of order and the soldiers continually violated hygienic laws in drinking from filthy water-holes and other polluted supplies. Quill, the army medical officer of Ceylon, takes the opposite view, and gives data that were obtained by him in a large camp formed at Diyatalawa in Ceylon for Boer prisoners of war. Here they are kept under discipline and all possibilities of water-borne typhoid guarded against so that this cause of the disorder can be excluded. He maintains that the infection there was air-borne, resulting from emanations from specifically infected latrines, infected dust, or bacilli-laden flies.

**9. General Pathology of Tumors.**—In these two lectures White reviews the subject of tumors. He thinks the classification based on embryology is unsatisfactory and gives the following classification based on their histologic types: 1. A class of organ tumors, or organomata, in which we can recognize distinct organs or parts of organs, not arranged, however, to form a body or part of a body, such as dermoids and teratomata. 2. We have a class of tissue tumors or histiomata in which we can recognize distinct tissues, but not arranged among themselves so as to form organs. This includes the connective tissue tumors (desmومات), lymphoid tissue tumors (lymphomata), muscle tumors (myomata), nerve tissue tumors (neuromata), and epithelial tissue tumors (epitheliomata), not including here, however, the malignant types, but rather the adenomas and endothelial growths. 3. We have cystomata or cell tumors, including: *a*, tumors of indifferent cells (blastomata); *b*, two kinds of tumors of the connective tissue cells, also the lymphoid tissue cells and the muscle cells (sarcomata); *c*, the types of epithelial cells (carcinomata). From this classification we arrive at a definition of tumor. It is a mass of cells, tissues or organs, resembling those normally present in the body, but arranged atypically. It grows at the expense of the body without subserving any useful purpose therein. With this scheme of classification we can conclude: 1. That every kind of tissue in the body has its representative tissue tumor. 2. Every kind of cell, with the exception of nerve cells, has its representative cell tumor. Cell tumors of nerve cells have not been described, but muscle cells are represented by myosarcoma, cartilage cells by chondro-sarcoma, and the different kinds of epithelial cells by the different kinds of carcinoma, etc. 3. Tumor formation is not an isolated process, but must be considered in its relation with other closely allied processes. The life history of tumors is next taken up. He does not support Cohnheim in recognizing them as originating in rudiments composed of embryonic cells, though that may be the case at times. They may take origin directly from the normal tissues or in the tissues of pre-existing tumors, or inflammatory products, and it is not necessary to suppose that the rudiment consisted of the same kind of tissue as that of which tumors are composed. The common factor in tumor formation is not to be found in the rudiment from which the tumor originates. Tumors grow mainly, even entirely, by centrifugal growth, that is, by proliferation of their own cells, but it is possible for the areas of origin to be extended by continuity. Centrifugal growth may be either central or peripheral. If the growth is central the growth will be definitely encapsulated; if peripheral the capsule will be more or less indistinct and the tumor will be infiltrating. The views that have been held as regards teratomata are several, but the author does not accept the parthenogenesis theory, or at least considers it unsatisfactory. The growth of tissue tumors takes place exactly as in normal tissues. As regards epithelial histiomata, White considers the connective tissue altogether secondary in importance to the epithelium in the growth. The growth of the cell tumors differs from that of the tissue tumors in that the growing portions consist of cells more or less loosely held together, but not forming definite tissues. These readily penetrate into the interstices of surrounding tissues. Any formed tissues which may be present in cytomata are of secondary, not primary, formation. In most cases tumors continue to increase in size, but may be limited by a change in structure such as ossification or calcification. Occasionally these tumors may decrease in size or disappear, even in the malignant forms, as has been shown by Sir Wm. H. Bennett. White thinks there is no evidence for the belief that cells of tumors are incapable of functioning. The sebaceous glands of a dermoid secrete sebum, the cells of adenoma or carcinoma of the intestine secrete mucin, and adenomata of the breast sometimes contain a milky fluid. Perhaps the most remarkable physiologic characteristic of tumor cells is the property they have of storing enormous quantities of glycogen, in which they exceed all the normal cells of the body. The question of the presence of glycogen in tumors is briefly considered; its origin and disposal are yet to be worked out. The pathologic changes to which tumors are

subject are the same as those to which a normal tissue is liable; various retrogressive processes, mucoid and fatty changes and calcification, necrosis, inflammation, etc. It will be seen that the histiomata and cytomata correspond respectively to simple and malignant types of a clinical classification. According to White the difference between a simple and malignant tumor is to be found in the manner in which it grows. In cell tumors the cells form no definite tissues. Tissue tumors, on the other hand, are primary in their formation from the first. He thinks the clinical features of malignant disease are very imperfectly treated in text-books. There seems to be no account taken of the temperature, and the urine and the blood have not received the attention they deserve. We need much more information on these points, especially as regards the excretion of nitrogen. In the second lecture he reviews certain theories as to the causation of tumors, first describing the cell structure and cell division and remarking that the centrosome and its associated achromatic substance or archoplasm have been strangely neglected by pathologists, notwithstanding they form such an important part of the cell. In malignant growths we find a deviation from the typical form of mitosis—asymmetrical mitosis, multipolar mitosis and amitosis or direct division. The endogenous formation of cells used to be thought a common event in carcinoma, though it has been more recently doubted. Personally, White has no doubt that it does occur. The causes of tumor growth are divided by him into extrinsic and intrinsic factors. Among the former he mentions irritants as important, and we must consider the possibility of the existence of a special extrinsic factor such as animal or vegetable parasite. This parasitic theory of carcinoma is quite extensively reviewed, but he concludes that it will not explain the production and growth of the primary tumor, nor the different species and the manner in which they breed true. We do not find a carcinoma giving rise to a secondary sarcoma process as might be expected were Gaylord and Plimmer's views correct. He doubts whether it will explain the metastases. It will not explain the frequency of malignant disease in certain organs or the rarity of it in certain others or why children possess such an immunity. He thinks we are justified in saying that malignant growths are not to be explained on the assumption of special extrinsic causal factors. The intrinsic causes are next considered and the question of the diminution of physiologic resistance is first mentioned. Ribbert's theory of tissue tension as restraining tissues from overstepping their natural bounds in normal conditions or the theory that ascribes the origin of tumors to loss of nervous control, neither of which are entirely satisfactory, are noticed, though the author believes that that of Ribbert is the most satisfactory one yet considered. He does not agree with Ribbert in assigning so great a part to connective tissue in tumor causation, though the difficulty of deciding the point is very great, as it is rare that one has a chance to examine a carcinoma at a sufficiently early stage. As regards nervous tissue, there is no proof, he says, that the loss of normal control can give rise to tumor formation, but there is, moreover, sufficient evidence that it does not necessarily do so, for example, in skin grafting. Beatson's suggestion that carcinoma of the breast is due in some way or other to ovarian influence has no basis other than that certain cases seem to improve when the ovaries are removed. This is not sufficient to form any groundwork for the theory of the origin of carcinoma, since the removal of the ovaries causes profound alterations in the metabolism of the body at large. In conclusion, he reviews Adami's theory, which agrees to a certain extent with Ribbert's that the initiation of a tumor is due to the alteration of the tissue tension, but also admits the action of prolonged stimulation if at the same time the cells are in some way or other prevented from performing their specific function. He criticises this theory in several points—its ignoring of the centrosome, etc., and the fact that it does not explain the penetration of epithelial cells into the surrounding tissues, which constitutes the essential lesion in carcinomas.

**11. Hemolytic Experiments.**—Petrie suggests certain methods and cautions in regard to hemolytic experiments, and summarizes the steps briefly as follows: "1. Use absolutely

fresh unclotted blood. 2. Prepare in test-tubes of equal size known percentages of the hemolysin in isotonic oxalate solution. 3. Add to each of the tubes exactly the same amount of blood and mix well. 4. Incubate tubes for the same length of time at 37 C. 5. Centrifugalize till all the corpuscles settle at the bottom of the tube, forming a sharp line of demarcation between the blood and the supernatant liquid. 6. In every experiment have control tubes containing isotonic salt solution alone. 7. In doubtful cases examine microscopically."

**12. Bacterial Hemolysin.**—Castellani describes his method of repeating experiments of E. and P. Levi to determine whether hemolysis was produced by the typhoid bacillus and in the main he has followed the methods of Neisser and Wechsberg. He tabulates his results and finds that the typhoid bacillus is capable of forming a hemolysin which produces a complete solution of erythrocytes in dog's blood, and the maximum amount of this is found in cultures about two weeks old. The dysentery bacillus gave equally positive results, thus presenting a new point of resemblance to typhoid bacillus. The colon bacillus did not exhibit any marked hemolytic properties, though he says he has only tested two races, and it is possible that other strains may have different properties. He has been successful in obtaining an anti-hemolysin for typhoid bacillus. For the purpose, a rabbit was treated with a filtered typhoid culture which contained active hemolysins. The serum of the rabbit developed anti-hemolytic properties 10 days after the injection of the typhoid culture, and on the addition of 0.05 c.c. of the serum of the treated rabbit to the amount of typhoid hemolysin capable of producing complete hemolysis of 1/20 of a c.c. of dog's blood, the solution of the dog's erythrocytes was inhibited. The serum of a normal rabbit used as a control did not exhibit any anti-hemolytic properties.

**13. The Pressor Substance of the Pituitary Body.**—Schaefer and Vincent have demonstrated the existence of two substances in the infundibular part of the pituitary gland, one producing a rise and the other a fall of blood pressure. They distinguish them as the pressor and depressor substances, the former being soluble in salt solution and insoluble in alcohol and ether, while the depressor substance was soluble in all three. These active substances are not destroyed by boiling. The pressor substance was found to produce its action on the heart and the peripheral arteries; its action is prolonged, and during its period of action a second dose is inactive or nearly so. Schaefer and Magnus find that this pressor substance, unlike suprarenal extract, produces no diminution in the form of the kidney when injected intravenously. The injection is followed by a diminution in the size of the spleen, intestines and extremities with an increase in the volume of the kidneys and a prolonged and pronounced diuresis which, however, lasts for a shorter period than the change in volume of the kidney. The medicinal use of the pituitary body has been rather uncertain, though a certain amount of results has been reported by various authors. A consideration of the physiological properties of the pressor substance of Schaefer and Vincent led Golla to try its effects on the human subject. He says: "its slowing action on the heart beat, unlike that of digitalis, appears to be due to a prolongation of the systole rather than of the diastole. The pressor substance would appear to act exclusively on the sarcoplasm. I have been unable to obtain any marked effect on the muscles of the amphibia rich in the rapidly contracting anisotropic elements such as the gastrocnemius. For clinical purposes the pressor substance purified by repeated washing of the alcoholic precipitate with ether obtained from 80 grains of the dried infundibulum was dissolved in 30 minims of normal saline. I found on injecting three minims of this solution into the mucous membrane of the lower jaw that a definite local vaso-constriction results; the mucous membrane remained blanched for about three-quarters of an hour for a considerable area round the point of injection. On injecting five minims subcutaneously into my right forearm there was a perceptible pallor of the finger nails for a few minutes. The pulse rate fell from 95 to 84, and the wave was appreciably fuller. A subcutaneous injection was next made on a patient

suffering from advanced Addison's disease under the care of Dr. H. D. Rolleston. The blood pressure in the radial artery before injection was found to be 120 millimeters of mercury by means of the Hill and Barnard sphygmometer. The pulse-rate was 100. Eight minims of the saline extract were injected subcutaneously into the forearm. Two seconds after the injection the patient complained of a sudden spasmodic contraction of the muscles of the arm and fingers. On feeling the pulse at the radial immediately after injection I was alarmed to find that it almost disappeared for a few seconds. That this symptom was due to the local muscular spasm with which it was coincident is confirmed by the fact that the arterial pulse in the left radial was found to be full and vigorous; 12 minutes after the injection the arterial pressure was found to be 150 millimeters of mercury and the pulse rate was 85. Previous to injection the patient had complained of feeling uncomfortably hot and a couple of minutes afterward he spontaneously remarked that all the heat seemed to have gone inside. Two hours after the injection the pulse rate was 89 and the pulse itself was much stronger and fuller. The patient still complained of feeling cold at the extremities. Three hours after injection the pulse rate was 95 and the blood pressure 135 millimeters of mercury. There were some pain and localized swelling at the site of the injection. There was marked diuresis during the twenty-four hours succeeding the injection; the urine was acid with a specific gravity of 1010. There was no glycosuria, an effect frequently noticed after suprarenal injection. I have taken considerable quantities of the pressor substance by the mouth, but have never been able to record any results, although the substance is unaltered by peptic digestion and is dialysable. The pressor substance would appear to be proteid in nature. It is precipitated from salt solution by trichloroacetic acid, gives biuret, xanthoproteic and Millon's reactions. It is not precipitated by saturation with a neutral salt, it is unaffected by peptic, but decomposed by prolonged tryptic digestion. The iodine found in the pituitary is not apparently in combination with the pressor substance. Its cardiac, vascular, and diuretic action would indicate that it may prove to be of service in cases of heart disease."

**14. Bubonic Plague.**—Galli-Valerio takes up the statement of Simond that the transmission of plague is largely due to infected fleas from rats and has investigated the subject thoroughly, studying the different species of fleas found on rats and their tendency to bite man. It appears that one species, the *P. serraticeps*, which has been gathered off rats, may bite man, but this must be very rare as only one observer has ever obtained it from the rat. He applies to the theory, however, evidence that he has gained from other sources, such as the facts that neither the German Commission nor Mr. Schotelius in India, and during the epidemics at Oporto, Glasgow or Naples, has evidence to prove the transmission of plague to man by fleas been found. He says also the facility with which it is possible to arrest an epidemic of plague where hygienic conditions are good and isolation properly carried out speaks against this theory. If Simond's hypothesis were correct, one might almost fold one's arms in consequence of the difficulty of preventing the diffusion of infected fleas. It requires to be demonstrated, not only that fleas pass from rats and mice to man, but from rat to rat. The question can only be solved by conveying to the body of human beings rat and mice fleas that have lived on plague rats. If the experiment is considered necessary he places himself at the disposal of the committee to undergo it.

**18. Congenital Ichthyosiform Erythroderma.**—Brocq describes a number of cases of this affection. It differs from ordinary ichthyosis by the distinctness of the erythroderma, by the rapid growth of the hair and nails, and by the localization of the lesions which affect principally the bends of the joints, exactly the reverse of the maximum localizations of true ichthyosis.

**20 and 21. Improved Technique for Radiotherapy.**—Oudin points out that the aim of radiotherapy should be to apply the therapeutic rays in as intense and brief a form as possible.

The light should be gauged to a certain standard. He recommends a current of 4 amperes, 15 volts, interrupted twenty times in a second. The tube should be placed with the anti-cathode 10 cm. from the skin, which brings the glass within 4 to 6 cm. The tube should be "soft," corresponding to a 5 cm. parallel or equivalent spark for a superficial, and an 8 cm. spark for a deep lesion. The first sitting should be for one minute, progressively lengthening the sitting by thirty seconds each day. The treatment must be suspended at the slightest symptom of erythema or disturbance, and postponed until the symptoms have entirely vanished. When it is resumed, the sitting should be three minutes shorter than the last before the erythema developed, and should never be allowed to reach this length again, in case of a superficial lesion, and only regain it very gradually in treating a deep lesion, suspending it again at the slightest symptoms of the reappearance of the erythema. The penetration of the rays should be determined so as to have them always of the same force. This can be accomplished by using Villard's osmo-regulator, Benoist's radiochromometer and Bécélère's spark measure or spintermeter, or their equivalents. The osmo-regulator controls the vacuum in the tube, and thus the penetrating power of the rays emitted by the tube can be increased or diminished at will. The electric resistance of the tube can be determined by measuring the length of the spark with the spintermeter, and brought to a certain standard by the osmo-regulator. The radiochromometer determines the kind of rays that are being emitted by the tube, by their power of penetration. It consists of a thin disc of silver set in the middle of a dozen flat rings made of aluminum of progressively increasing thickness, all numbered. The aluminum ring through which the rays pass with a penetrating power exactly equal to that with which they pass through the central silver disc, is the measure of the penetrating power of the rays. The little instrument is mounted like an opera glass with a fluorescent screen instead of lenses. The operator can tell by a glance through it the exact degree of the penetrating power of the rays from the tube. Static electricity has proved most effective in Ondin's experience. The latest researches have confirmed the fact that the therapeutic and injurious effects of the  $x$ -rays are due exclusively to the  $x$ -rays themselves and not to the electricity.

**28. Prognosis of Operation for Glaucoma.**—Mendel reports from Hirschberg's ophthalmic clinic that during the last seven years 234 patients have been treated for glaucoma and 258 eyes operated on. Of this number 83 were men, 144 women and 7 children. No operation was performed in 15 cases. The best results were attained by iridectomy in acute inflammatory glaucoma: 82.2 per cent. comparatively or completely cured, and 77.1 per cent. in chronic inflammatory glaucoma. It also improved or at least prevented further injury to the sight in the cases of simple hypertension. The results confirm on the whole those obtained in the previous 569 operations for glaucoma. Iridectomy has maintained its supremacy during the twenty-five years' experience in the clinic, but not to the complete exclusion of other operations. The second eye was never operated on until the first had recovered completely from the intervention. Enucleation was required in 31 cases during the last seven years on account of pain. Haab has recently published similar statistics showing 77 per cent. comparative or complete cures in acute inflammatory glaucoma, and 71 per cent. in simple glaucoma, with 40 per cent. cured under treatment with myotics.

**30. Sanatorium and Tuberculin Treatment in Tuberculosis.**—Weicker claims that the results of sanatorium treatment ought not to be called permanent cures but merely "postponing the fatal termination." The average thirteen weeks' course in a sanatorium is altogether inadequate and consequently adjuvant measures should be continued after dismissal. He thinks experience has shown that tuberculin administered in repeated courses, as a supplement to the sanatorium, offers brilliant prospects of cure of otherwise doomed cases. [See below.]

**31. Symptoms and Treatment of Chronic Distension of**

**the Lungs.**—For years Riegel has been using atropin in subcutaneous injections to arrest and cure neuroses of the vagus. It is especially effective in asthma from this cause.

**32. Tympanites and Phantom Tumors.**—Talma has observed several cases of tympanites occurring each side of the contracted recti muscles. In a recent case this partial tympanites simulated an abdominal tumor, as the upper abdominal muscles were relaxed while there was partial contraction of the transverse muscles and at the same time pronounced contraction of the diaphragm. This combination presented the aspect of an abdominal tumor. There were no stigmata of hysteria, but the patient was evidently a hysteric. The tumor persisted during a supposed sleep, which was probably feigned. It subsided spontaneously during narcosis. Talma also witnessed the development of a typical, hysteric general tympanites in a physician with tendencies to hysteria, whose attention had been attracted to his abdomen by the unusually severe borborygmus of one of his patients. Laxness of the abdominal muscles with contraction of the diaphragm is the cause of the general tympanites.

**34. An Artificial Esophagus.**—Trendelenburg has suggested that the patient should chew each mouthful and then eject it into the funnel-shaped opening of the tube entering the gastric fistula. Spiegel has devised an artificial esophagus on Trendelenburg's principle. The distal end of the tube entering the gastric fistula is inserted in a fistula made for the purpose in the esophagus just above the stricture. The patient masticates and swallows each mouthful normally. It passes down the throat into the upper end of the esophagus, and thence through the artificial tube esophagus into the stomach. Fluids and soft foods are thus ingested without difficulty, but solid food requires some imitation of the natural peristaltic movements to force it along. This is accomplished by a contrivance attached to the tube by which a small ball can be rolled along it. He has also constructed a clockwork device which automatically imitates the peristalsis. The artificial esophagus is worn under the clothing, and is taken out of the esophagus fistula at night and replaced by a stopper to keep it from closing. It is illustrated in the original article, and is to be tried at von Mosetig's clinic.

**35. Embolism of the Lungs After Laparotomies, Especially in Cases of Appendicitis.**—Oppenheim has witnessed five cases of embolism of the lungs after surgical intervention on account of appendicitis. One case was fatal. Acute appendicitis is frequently accompanied by more or less diffuse peritonitis. The toxins generated in the course of the peritonitis affect the heart injuriously, and it also suffers from the forcing up of the diaphragm by inflammatory processes below. The thorax is unable to expand normally in consequence, and this interferes with the heart action. The quantity of blood received from the veins and forced into the arteries is reduced. These conditions favor the development of thrombi. By the time surgical intervention is indicated for the appendicitic abscess, the patient has already well-developed thrombi and is ripe for embolism. Many cases are on record in which this complication of an appendicitic abscess was noted, even in the absence of any operation. It may develop without previous inciting cause, but it usually follows some unusual or rapid muscular effort. In order to reduce the possible dangers from this cause, all patients requiring a laparotomy are moved without effort on their part, and the results have confirmed the advantages of the measure. A square of sail cloth is slipped under the patient on the operating table. A strong frame is then placed over him and the sail cloth sheet is buttoned to the frame. The patient thus lies in a kind of hammock and is lifted by the frame and carried to his bed where the sheet is unbuttoned and may be left under him, ready to carry him back to the table when the dressings are to be changed. Before any laparotomy the condition of the heart and pulse should be investigated. Oppenheim suggests that the moral effect of a laparotomy under local anesthesia may be as injurious to a subject with a weak heart as general narcosis. This assumption is sustained by the experience of Mikulicz and Gottstein, who

report that lung affections seem to occur with the same frequency after local as after general anesthesia.

**36. Present Status of Tuberculin Treatment.**—The combination of several courses of tuberculin treatment with treatment at a sanatorium has accomplished in Weicker's and Petruschky's experience, results far surpassing those achieved by any other method. It cures cases in which either alone would have proved ineffective. Goetsch has attained good results with a single protracted course of tuberculin treatment requiring from six weeks to twenty-seven months as described in *THE JOURNAL* of July 13, p. 151. Recovery from tuberculosis is a slow process. Few persons can spare the time and money requisite for such a course, but the combination of an ambulant course of tuberculin, then sanatorium treatment for a few weeks, followed by resumption of ambulant tuberculin treatment, is within the reach of almost every one. The results are even better than those reported by Goetsch, which have marked an epoch in the treatment of tuberculosis. Petruschky thinks that thousands of lives have been sacrificed in the last ten years, which might have been saved if the reaction from the first enthusiasm in regard to tuberculin had not been so exaggerated. We know now how to avoid excessive reaction and how to keep the doses of tuberculin below the fever-producing point. By combining it with sanatorium treatment to strengthen the patient, the cures from the latter will be increased from the present figures of 44.4 per cent., in the first lung stage, to 90 and 100 per cent.; and in the second stage, from 16.7 per cent. to 40 and 50 per cent. Spengler, Turban and Goetsch have long combined the sanatorium and tuberculin treatment, and Petruschky's innovation consists in the idea of frequent repetition of courses of treatment—the "Etappen-idea," that is, treatment in stages. He proclaims that early diagnosis by means of tuberculin should be promoted in every way.

**37. Detachment of the Retina in Nephritis of Pregnancy.**—Helbron has collected twenty-one cases and has observed another of this complication of nephritis. The retina soon became attached again, but vision was not always restored to normal. On account of the danger of loss of eyesight, the pregnancy should be interrupted as soon as possible, he asserts, when this complication occurs.

**38. Bacteriolytic Action of Nucleases as Factor in Immunity.**—Later researches have fully confirmed the previous assertions of Emmerich and Löw in regard to the bacteriolytic action of the enzyme, pyocyanase, derived from the bacillus pyocyanus. A minute quantity is able to kill in a few seconds millions of diphtheria, cholera, plague and typhoid bacilli, and streptococci. The enzyme of the pyocyanus is therefore heteroform, while that of other bacteria is homoform. The bacteriolytic enzymes become transformed into highly molecular albuminoid compounds—the "Immunoproteidines"—in the blood, and artificial immunity is based on the bactericidal action of the enzymes.

**39. Tests of the Bacillus Pathogenic for Rats.**—Issatschenko now proclaims that the bacillus he has been cultivating since 1898, originally derived from gray rats, is not pathogenic for horses, oxen, pigs, dogs, cats, fowls or sheep, even when fed to the animals in large amounts. On the other hand, it killed 431 out of 443 rats to whom it was fed. Tests throughout Russia with bouillon cultures sent for trial were successful in 70.1 per cent.

**42. Production of Remarkably Virulent Bacterial Toxins with Selected Culture Media.**—A series of tests and experiments are described by Zinno, which show that the nature of the culture medium is the most important factor in the development of bacterial toxins. He found digested brain substance most remarkable in this respect and ordinary brain substance next. The proportions in case of tetanus toxin were 12,000,000 and 7,000,000 to 1,800,000 in ordinary bouillon with serum. In the case of diphtheria toxin, they were respectively 180,000 and 150,000 to 15,000. By selection of the medium in this way it is possible to obtain toxins much more virulent than has hitherto been supposed possible. His experiments seem to

demonstrate that diphtheria toxin is derived from albuminoid molecules already present in the culture material, and that it is not a genuine product of synthesis.

**44. Differentiation of the Typhoid and Colon Bacilli by Neutral Red.**—The agar culture medium is tinted with a solution of neutral red before it is sown with the suspected material. The cultures of coli reduce the stain, while nothing of the kind occurs in the typhoid cultures. Wolff confirms that this method of differentiation is always reliable, and enables the typhoid bacillus to be easily isolated from the feces. It has a single disadvantage, namely, that the differential diagnosis can not be made directly from the plate.

**45. Suprapubic Cystoscopy.**—The fistula consecutive to a suprapubic cystotomy was utilized by Kraske for visually inspecting the bladder, inserting the cystoscope through the fistula after first dilating it with lammaria. In another case a permanent canula was inserted in the opening made by puncture to relieve the retention in a patient with hypertrophied prostate, and the cystoscope was introduced in the same way. It was impossible to introduce the cystoscope through the natural routes in either case. The oversight of the bladder afforded by this method of cystoscopy was so surprisingly extensive and complete, that he suggests its adoption as a routine technique in cases impossible to inspect by the ordinary methods. It is especially advantageous in case of hypertrophied prostate as it allows the entire mechanism of the obstacle to be examined in detail. Without the knowledge thus afforded, it is impossible to perform the Bottini operation in a rational manner. All intravesical operations can be performed with greater facility when illuminated by this suprapubic cystoscopy. It can be done by dilating the opening a few days after puncture and then introducing the cystoscope, or the puncture can be made with a trocar large enough to admit the latter. The simplest method, however, is to use a cystoscope made for the purpose with a trocar tip, so that it can be pushed directly into the bladder. The optical part can be drawn out and the empty shell serve for the irrigation of the bladder if desired. Kraske illustrates a puncture-cystoscope made on this plan.

**47. Rupture of the Uterus in Cicatrices.**—Peham reports three cases from Chrobak's clinic of rupture of the uterus occurring in women who had had a rupture during previous deliveries. Even the cicatrix from a Cesarean operation is liable to rupture during a subsequent birth. The greater frequency of rupture in pluripare is probably due to the further laceration of cicatrices left from preceding childbirths. The pregnancy should be interrupted in women who have suffered from an extensive rupture in a previous delivery, especially when it was treated by tamponing and draining alone. He advises removing the uterus as a routine measure when laparotomy has to be performed on account of a ruptured uterus unless the organ can be solidly sutured.

**54. Congenital Alkaptonuria.**—Garrod reports 11 cases of alkaptonuria which occurred in four families. The parents were first cousins in three of the families, but there was no consanguinity in the other. Each family had more than one child thus affected. Meyer observed a case where the parents were closely related. These facts suggest that the alkaptonuria is a chemical deviation from the normal standard, analogous to the more common anatomic malformations. In the case of one infant, the dark stains appeared on the diaper for the first time fifty-three hours after birth, not until the child had taken the mother's milk.

**56. Early Diagnosis of the Typhoid Bacilli.**—Polacco and Gemelli found typhoid bacilli regularly in the roseola on fifty patients in the early stages of typhoid fever. The bacilli are so scanty that they require a liquid medium for further growth. "Vaccinostyle Marechal" was used for the culture medium and the differentiation of the culture was possible in twelve to sixteen hours. [See editorial on p. 586 of *THE JOURNAL*, March 1.]

**57. Toxic Effects of Sulphite of Soda Used as a Meat Preservative.**—Kionka reports the results of a study of the

toxic effects of "Präservesalz," a product used within the last fifteen years by German butchers for meat (especially minced meat) preservation. It consists mainly of an impure sulphite of soda with sodium sulphate and sometimes a proportion of common salt. In former communications he had maintained the toxic action of sodium sulphite, but his conclusions had been disputed, hence this later investigation. While the animals employed (dogs) showed no special symptoms during the 65 to 67 days of feeding with from 2/3 to a gram of sulphite of soda or from a little less than 1/2 gram of "Präservesalz" to 7 grams, excepting in the case of two pregnant females who aborted, the experiments revealed serious lesions, vascular obstructions, hemorrhage, inflammations in the heart, lungs, kidneys and elsewhere. The findings, he holds, confirm his earlier observations, viz., that the continued ingestion of sulphite of soda even in the usual quantity employed as a meat preservative, causes in dogs a serious intoxication of the blood, producing vascular clogging, hemorrhages and inflammatory degenerative changes in the vital organs, which are to be considered as the result of this action on the blood. The abortion in the two pregnant animals is noteworthy as corresponding with the long known fact of the bad effects of the sodium and magnesium sulphites on pregnant women. There are few other positive facts known in regard to the action of these salts on the human species, but the above is significant as showing the analogy between man and dogs in this respect. Kionka therefore maintains that it is necessary to forbid the use of the sulphite salts for preservation of foodstuffs.

**58. Myelogenous Leukemia.**—Two cases of this disease with clinical histories and blood examinations are reported by Hirschfeld and Tobias. In one the history extends to the post-mortem, the other passed out of observation after about six months of treatment. The blood findings showed very wide variations in the relative proportions of the different types of leucocytes, especially in the great and small mononuclear cells, the eosinophiles and the mast-cells, while the polynuclear neutrophiles showed the least variation. This polymorphism was much more marked in the second case than in the first. In both, the mast-cells and the smaller mononuclears were absent in some of the examinations. There were also irregularities in the granular contents of the cells, in their staining reactions, etc. In some of the polynuclear cells there was an absolutely granular free protoplasm; some of the granules of the myelocytes and eosinophiles took on with the triacid stain a decidedly bluish tinge. There were variations also in the form and granular contents of the mast-cells, some of the latter possessing granules with other color affinities besides those of the regular mast-cell granules. The second case reported suffered from tuberculosis as well as from leukemia, a combination which, though rare, has been observed by a number of authorities. The tuberculosis may be imposed upon the leukemia or the latter may call out into activity an existing latent condition. The authors investigated in these cases for proof of Löwit's statement as to the presence of protozoa in leukemic blood. They found bodies similar to those he describes, but not in all the forms, and there were color differences also, which they suggest may be due to the different reagent, Merck's thionin instead of Thalheim's used by Löwit. They do not regard these as of parasitic nature; inoculation experiments were not favorable to this view, producing neither leukemia nor reproducing the alleged parasites.

**61. Atropin Treatment of Ileus.**—Weber concludes from a study of the cases in the literature and his own experience, that previous treatment with opium is the explanation of the inefficacy of small doses of atropin in the treatment of ileus, and also of the tolerance for large doses. Thirty-nine cases have been reported treated with atropin, and only four failed to respond to the injection. Atropin therefore is decidedly to be preferred to morphin. According to experience, if the patient has already taken opium, a subcutaneous injection of .005 atropin can be administered with confidence that in nearly every case the ileus will be relieved in ten to twelve hours. If the symptoms of ileus still persist, the dose can then be re-

peated unless symptoms of intoxication develop. If this amount, .01 atropin, prove ineffectual in the course of twenty-four hours, the surgeon must be summoned. But if the patient is not already under the influence of opium, the first dose should not be more than .002, followed if necessary by .005 twelve hours later. Atropin treatment is not contra-indicated in any ileus. Even in cases of incarceration which require surgical intervention, the atropin relieves the pain and after the operation induces a copious, harmless stool. Ileus appearing after an abdominal operation should be treated with atropin and not with opium. The atropin may possibly release impacted feces in cases of large scrotal hernia in elderly patients. Atropin should be given a trial in perityphlitis. Any toxic symptoms that develop can be controlled by an injection of morphin. The stomach and intestines should be rinsed out in every case of ileus.

**71. Traction Diverticulum in the Esophagus.**—Ribberts has collected forty specimens of traction diverticulum. He attributes it to some congenital tendency or defective development. An inflammatory process may develop along the lymphatics near the esophagus and the tip of the diverticulum may become involved in the process with consecutive contractions and adhesions. These enlarge the pocket and result in the typical malformation.

**73. Idiopathic Cutaneous Sarcoma.**—Philipson presents the results of study of ten cases of Kaposi's idiopathic sarcoma of the skin. It demonstrates that some virus penetrating into the skin from without induces at its entering point a proliferation of spindle cells or blood or lymph angiomas. After it has remained located at this point for a time, it penetrates into the circulation and reaches the skin again by the way of embolism. This time the hands and face are principally affected. It spreads thence gradually towards the center by the lymph route, affecting the arms, legs and trunk. Occasionally acute embolic exacerbations are observed, and new foci and finally internal metastases develop. The local action of the virus is limited, and the proliferations atrophy in time. The acute irruption of the virus into the circulation causes hemorrhages from the veins. In its general course the affection has some analogy to syphilis. It testifies to the fact that cellular neoformation can be induced by an external stimulus. This has hitherto been accepted only for hyperplastic proliferation.

**75. Necrotic Inflammation of the Esophagus and Stomach in Scarlet Fever.**—Fraenkel states that the necrosis in the two observations he describes was the direct effect of the streptococci which had colonized in the lymphatic canaliculi in the wall of the esophagus and stomach. In one the stomach alone was affected. The process is both erysipelatous and phlegmonous in its characteristics. It is both anatomically and etiologically identical with laryngeal erysipelas, and the same treatment is required as for analogous affections of the skin and subcutaneous tissue, that is, incision of the edematous mucosa.

**80. Treatment of Spastic Aphonia.**—In the case described by Wicherek, the patient was a healthy young soldier who had been unable to utter a sound for eight months after a scuffle with a comrade who had slapped him in the face and choked him. The traumatism was slight and exclusion of other causes suggested the possibility of hysteria, although no stigmata could be discovered. Faradization of the throat muscles, systematic exercises in speaking and chloroform narcosis all proved ineffectual. The mucosa of the pharynx and larynx was then swabbed with a 20 per cent. solution of cocain, while the tongue was pulled out and held. The patient was then instructed to utter the vowel sound of A, repeating it after another person. After great effort he was able to accomplish this, and repeat it until he could say it fluently. Other vowel sounds were then taught him in the same way, while he put his fingers on the larynx of the person instructing him. Short words and sentences were then tried. At the end of an hour of this exercise he was so exhausted that he had to go to bed. It was repeated again every day, and by the fourth, his aphonia had been entirely conquered.

**81. Mental Development of Cretinous Child Under Thyroid Treatment.**—Heller states that he has never seen in the literature the announcement that thyroid treatment has been systematically employed in schools for mentally deficient children to transform untrainable into trainable subjects. He thinks that the combination of thyroid with pedagogic treatment promises better results than hitherto attained, and describes a case in detail to illustrate the unexpected advantages derived from this combination in treatment of a supposed hopeless cretin and idiot.

**92. Fate of Diphtheria Bacillus in Alimentary Canal.**—Süsswein states that the records of the St. Anna Children's Hospital at Vienna show that diphtheria of the stomach was noticed four times in 146 diphtheria cadavers in six months of 1893, that is, before the introduction of serum treatment. During all the years since there has been only one case known of diphtheric lesions of the stomach. This was a child moribund when first seen. He has recently undertaken to solve the question of the fate of the diphtheria bacillus in the alimentary canal. He examined 8 cadavers and found diphtheria bacilli in the stomach in 4, but it was impossible to grow cultures from more than 2, and in these cases the bacilli displayed an attenuated vitality. He never found them in the intestines. Researches on the bactericidal power of the acids in gastric juice showed that diphtheria bacilli were killed in an hour when the gastric juice contained even as little as .04 per cent., of uncombined hydrochloric acid, .08 per cent. of lactic acid and .054 per cent. of hydrochloric acid in combination. This is the first time, he adds, that the demonstration of an antiseptic power by hydrochloric acid in combination has been offered. Gastric juice from 5 diphtheria patients proved to possess sufficient parasitic action to kill the bacilli although it contained much less acid than normal juice, and no hydrochloric acid not in combination could be discovered. A hemorrhagic erosion in the gastric mucosa would afford favorable conditions for the propagation of bacteria, but they are destroyed by the gastric juice except in the rare cases of total or partial lack of acid. Baner and Dentsch have established that the secretion of gastric juice is more active after injection of antidiphtheria serum, which explains the lesser frequency of diphtheria of the stomach since serum treatment was inaugurated.

**84. Experiences with Hydrophobia.**—In Pampoukis' experience as superintendent of the Athens Pasteur Institute, he found the incubation was less than a month in 63.4 per cent. of 52 animals which had died from natural rabies; two months in 26.9 per cent., and still longer in 9.6 per cent. The disease first manifested itself during the first month in 8 per cent. of 51 persons who died from hydrophobia; in 54 per cent. during the second month; in 24 per cent. during the third month, and in the fourth month or later, in 14 per cent. The incubation lasted six to seven months in 5 subjects and twelve months in 2. It was shortest in persons bit in the face by a wolf, being from fourteen to thirty-one days in these cases.

**85. Alcoholism in Greece.**—Notwithstanding the widespread consumption of wines in Greece, alcoholism is practically unknown. This is explained by Foustanos as due to the purity of the wine. It is made exclusively from grapes and thus contains the most harmless form of alcohol. The ancient Greeks had no word in their language to express alcoholism, which testifies to the fact that it was also unknown among them.

**88. Infantile Gastro-Intestinal Affections.**—Meirelles proclaims that the diagnosis of gastro-intestinal affections should be based on the chemical reaction of the saliva, stomach contents or stools, and not on the clinical conceptions of gastritis, enteritis and diarrhea. Infantile gastro-intestinal disturbances are rarely idiopathic. Fully 90 per cent. are due to the contents rather than to the alimentary canal itself. He determines the acidity or alkalinity of the saliva, vomit or stools with litmus paper, and treats the disturbances by merely neutralizing the excess of either acid or alkali. He has been treating infants for nine years on these principles, with invariable success. It is a scientific method, and sweeps away at one stroke all the confusion of gastritis, colitis and all other terms which

express in reality merely the results of excessively acid or excessively alkaline conditions. He has found a 2 per cent. solution of lactic acid effectual in restoring abnormally alkaline conditions to normal, while in case of a very acid reaction, he administers every hour a teaspoonful of a mixture consisting of 60 gm. of fluid magnesia; 2 gm. of sodium bicarbonate, and 1.5 gm. of sodium salicylate. He suppresses milk for twelve hours and keeps the child on water in severe cases. The alkaline mixture is given before and after taking well alkalized milk. Boas has pointed out that the albuminoids are well digested in a hyperacid medium, while the carbohydrates and fats are imperfectly digested. The neutralization is supplemented, of course, by calomel and other measures as indicated by the individual case. In case of stomatitis or other lesions of the mouth, an excessively acid saliva maintains them. The mouth should be disinfected, but not with boric acid, as this directly adds to the acidity and aggravates the lesion. A good mouth wash in such acid cases is 6 parts each of sodium salicylate and borax in 200 parts of water. When the vomit or stools or both give an alkaline reaction, he administers a teaspoonful of a 2 per cent. solution of lactic acid every ten or fifteen minutes. He adds to his communication the case-report of an adult treated on these principles, with prompt cure of the gastro-intestinal affection.

**89. Success of Antiplague Vaccination at Campos.**—Pinto is the official chief of the health department of the state of Rio, and this article reports the results of the preventive antiplague vaccination undertaken at Campos during the recent widespread epidemic of plague there. He states that the vaccine was obtained from Terni's Institute at Messina or from the national vaccine bureau, and 1803 persons were vaccinated, all at their homes. One exhibited symptoms of the disease immediately after the vaccination, the other thirty-two days afterward. Of the total number, therefore, only one contracted the plague after being vaccinated, with the exception of the one who was already under the influence of the disease as above mentioned. The one plague patient had the disease lightly. The plague seems to be of a mild character in Brazil, and consequently it is possible that the vaccination had better chances for success owing to some climatic or racial lack of predisposition on the part of the inhabitants. In one district a person was encountered who refused to be vaccinated, and he was the only one who contracted the plague. Many of the vaccinated persons lived or were in contact with plague patients, and nearly all were of the poorer classes, the very ones most predisposed to acquire the disease. Pinto concludes that the facts of the "brilliant, magnificent, amazing effect of the vaccine" in his experience speak louder than words in its favor.

## Queries and Minor Notes.

### EHRLICH'S TRIACID STAIN.

MADISON, IND., Feb. 3, 1902.

To the Editor:—Will you kindly publish the formula for making Ehrlich's triacid solution test for mucus? W. A. M.

ANS.—The Ehrlich triacid stain is made up as follows:  
Saturated aqueous solution of orange G... 120 parts  
Acid fuchsin ..... 80 parts  
Methyl-green ..... 100 parts  
Distilled water ..... 300 parts  
Absolute alcohol ..... 180 parts  
Glycerin ..... 50 parts  
Never shake the solution. Pipet from the top what is needed for use.

### New Patents.

Patents of Interest to physicians, February 4 and 11:  
692,497. Making acetyl-cellulose. Maximilian C. L. Althausse. Billwader-an-der-Bille, near Hamburg, Germany.  
692,503. Reversible bandage case. Samuel Bottomley, Providence, R. I.  
692,251. Dummy lung-tester. Edmund and U. S. DeMoulin. Greenville, Ill.  
692,437. Hydrochlorid of cinnamyl-quinlin, and making same. Gotthold Fuchs, Bleibach, Germany.  
692,303. Wrinkle-removing device. Julia E. Kendall, Boston, Mass.  
692,703. Rubber glove. Jacob Pfeiffer, Jr., Akron, Ohio.  
692,704. Rubber glove. Jacob Pfeiffer, Akron, Ohio.

692,360. Artificial limb. James F. Rowley, Chicago.  
 692,798. Tip for atomizers and nebulizers. Cyrus J. Seltzer, Philadelphia.  
 692,485. Atomizer and nebulizer. Cyrus J. Seltzer, Philadelphia.  
 692,552. Combined atomizer and nebulizer. Cyrus J. Seltzer, Philadelphia.  
 692,721. Atomizer. Cyrus J. Seltzer, Philadelphia.  
 692,722. Atomizer. Cyrus J. Seltzer, Philadelphia.  
 692,375. Nozzle. Charles A. Snider, Jersey City, N. J.  
 692,554. Chair for therapeutic purposes. Johann J. Stanger, Ulm, Germany.  
 692,803. Stump-socket for artificial limbs. Leo Stumpf, Covina, Cal.  
 692,556. Artificial eardrum. Anton von Suchorzynski and M. Kohl, Breslau, Germany.  
 35,655. Design, massage roller. Charles J. Bailey, Newton, Mass.  
 693,345. Vaginal speculum. Albert J. Bearer, New Kensington, Pa.  
 693,138. Preparing and inclosing surgical ligatures. Robert W. Johnson, New Brunswick, N. J.  
 693,861. Tray-support for physicians' tables. Wm. H. Kersey, Indianapolis.  
 693,140. Mouth mirror. Wm. E. Knight, Ostrander, Ohio.  
 693,156. Pharmaceutical implement. Marz F. Rochester, Ingle-side, Md.  
 692,920. Fountain syringe holder. Gustav Schirmer, Chicago.  
 693,358. Vaginal irrigator. Henricus W. Westlake, Los Angeles, Cal.  
 35,714. Design, blank for specula. Charles J. Pilling, Lansdown, Pa.  
 35,715. Design, blank for speculum blades. Charles J. Pilling, Lansdown, Pa.  
 35,716. Design, blank for speculum blades. Charles J. Pilling, Lansdown, Pa.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., February 13 to 19, 1902, inclusive:

Henry P. Birmingham, major and surgeon, U. S. A., member of an army retiring board at Fort Leavenworth, Kan.  
 Jerome S. Chaffee, lieutenant and asst.-surgeon, U. S. A., on the completion of the course of instruction at the Army Medical School, Washington, D. C., to report for duty at the General Hospital, Fort Bayard, N. M., to relieve Lieutenant Louis T. Hess, asst.-surgeon, U. S. A.  
 Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., to report in person to the president of the Army retiring board convened at Fort Leavenworth, Kan., for examination by the board.  
 Clyde S. Ford, lieutenant and asst.-surgeon, U. S. A., leave of absence extended fourteen days.  
 Charles E. Freeman, contract surgeon, now at San Francisco, Cal., to report for transportation to Manila, P. I., for assignment in the Division of the Philippines.  
 Joseph N. Henry, major and surgeon, Vols., now at Philadelphia, Pa., on leave of absence, will proceed on the expiration of his leave to Fort Slocum, N. Y., to accompany recruits via San Francisco, Cal., to Manila, P. I., where on arrival he will report for assignment in the Division of the Philippines.  
 Louis T. Hess, lieutenant, asst.-surgeon, U. S. A., on being relieved from duty at the General Hospital, Fort Bayard, N. M., to proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.  
 Carl R. Hexamer, captain and asst.-surgeon, Vols., now at San Francisco, Cal., is honorably discharged from the service of the United States, to take effect Feb. 28, 1902.  
 Allen D. McLean, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect Feb. 17, 1902.  
 Ernest E. Roberts, contract surgeon, now at Las Cerillos, N. M., to the Division of the Philippines, via San Francisco, Cal.  
 Paul Shillock, major, surgeon, U. S. A., member of an army retiring board at Fort Leavenworth, Kan.  
 Sanford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., from Columbus Barracks, Ohio, to San Francisco, Cal., en route for assignment in the Division of the Philippines.  
 Llewellyn P. Williamson, lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to duty at Columbus Barracks, Ohio.  
 Marlborough C. Wyeth, major and surgeon, U. S. A., leave of absence for one month granted on his arrival in the United States.

### Appointments, Promotions, Retirements, Etc.,

recorded in the Adjutant-General's Office between Jan. 15 and Feb. 15, 1902:

*U. S. Army, Promotions.*—To be assistant surgeons general, with rank of colonel, Jan. 1, 1902: Lieut.-Col. Benjamin F. Pope, deputy surgeon-general, and Lieut.-Col. James P. Kimball, deputy surgeon-general. To be deputy surgeons-general, with rank from Jan. 1, 1902: Major John Van R. Hoff, surgeon, and Major George W. Adair, surgeon. To be surgeons with the rank of major: Captain Ogden Rafferty, asst.-surgeon, Dec. 9, 1901, Captain James D. Glennan, asst.-surgeon, Jan. 1, 1902, and Captain Alfred E. Bradley, asst.-surgeon, Jan. 1, 1902.

*Died.*—Colonel Benjamin F. Pope, assistant surgeon-general, Feb. 14, 1902, at Manila, P. I.

*U. S. Volunteers, Appointments.*—To be surgeons, with the rank of major: Captain William D. Shelby, asst.-surgeon, Vols., and Captain Lewis T. Griffith, asst.-surgeon, Vols. To be asst.-surgeons, with rank of captain: Thurston Smith, of Indiana, contract surgeon; Hyman M. Cohen, of Maryland, contract surgeon, and Harold L. Coffin, of Maine, contract surgeon.

*Honorably Discharged.*—Captain Frank D. Pease, asst.-surgeon;

Captain Frank A. E. Disney, asst.-surgeon, and Captain John T. H. Slayter, asst.-surgeon.

*Commission Vacated by New Appointment.*—By Major James D. Glennan, surgeon, U. S. A., his commission as major and surgeon, U. S. Vols., Jan. 1, 1902.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Feb. 20, 1902.

Surgeon J. J. Kinyoun, granted leave of absence for two months and three days from February 16.

P. A. Surgeon M. J. Rosenau, detailed to represent the service at meeting of the New York Academy of Medicine, to be held at New York City, February 20.

P. A. Surgeon E. K. Sprague, to proceed to Port Huron, Mich., for special temporary duty.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence for fifteen days from February 15, on account of sickness.

A. A. Surgeon J. A. Moncure, granted leave of absence for 30 days from February 15.

A. A. Surgeon B. Y. Harris, granted leave of absence for fifteen days from February 15.

A. A. Surgeon S. H. Hodgson granted leave of absence for thirty days from March 1.

A. A. Surgeon W. R. Hunter, granted leave of absence for two weeks from February 1.

Senior Pharmacist F. H. Peck, relieved from duty at St. Louis, Mo., and directed to proceed to Evansville, Ind., and report to medical officer in command for duty and assignment to quarters.

Junior Pharmacist C. W. Stephenson, upon being relieved from duty at Evansville, Ind., to proceed to St. Louis, Mo., and report to medical officer in command for duty and assignment to quarters.

#### RESIGNATION.

Surgeon J. J. Kinyoun resigned to take effect April 19, 1902.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 21, 1902.

#### SMALLPOX—UNITED STATES.

California: Eureka, Jan. 27, 1 case imported; Humboldt County, Jan. 27, 5 cases in lumber camps; Los Angeles, Feb. 1-8, 3 cases; Sacramento, Feb. 1-8, 1 case; San Diego, Feb. 1-8, 1 case; San Francisco, Feb. 1-8, 4 cases.

Colorado: Denver, Dec. 28-Feb. 8, 12 cases.

Illinois: Belleville, Feb. 8-15, 2 cases.

Indiana: Evansville, Feb. 8-15, 5 cases.

Iowa: Clinton, Feb. 8-15, 1 case.

Kentucky: Covington, Feb. 8-15, 11 cases; Lexington, Feb. 8-15, 2 cases.

Louisiana: New Orleans, Feb. 8-15, 1 case.

Maine: Portland, Feb. 1-15, 6 cases.

Maryland: Baltimore, Feb. 8-15, 1 case.

Massachusetts: Boston, Feb. 8-15, 38 cases, 6 deaths; Cambridge, Feb. 8-15, 5 cases, 1 death; Everett, Feb. 8-15, 3 cases; Malden, Feb. 8-15, 1 death; Medford, Feb. 8-15, 1 case; New Bedford, Feb. 8-15, 1 case; Somerville, Feb. 8-15, 1 case; Taunton, Feb. 8-15, 3 cases; Weymouth, Feb. 1-8, 1 case.

Michigan: Bay City, Feb. 8-15, 3 cases; Detroit, Feb. 8-15, 5 cases; Grand Rapids, Jan. 29-Feb. 15, 3 cases; Ludington, Feb. 8-16, 2 cases; Winona, Feb. 1-8, 1 case.

Nebraska: Omaha, Feb. 8-15, 46 cases, 1 death; South Omaha, Feb. 1-17, 61 cases.

New Hampshire: Nashua, Feb. 8-15, 2 cases.

New Jersey: Camden, Feb. 8-15, 3 cases, 1 death; Jersey City, Feb. 8-16, 22 cases; Newark, Feb. 8-15, 20 cases, 7 deaths.

New York: Binghamton, Feb. 8-15, 9 cases; Mount Vernon City, Feb. 18, 1 case; New York, Feb. 8-15, 58 cases, 14 deaths.

Ohio: Cincinnati, Feb. 7-14, 13 cases; Cleveland, Feb. 8-15, 1 case; Hamilton, Feb. 8-15, 5 cases; Youngstown, Feb. 1-8, 3 deaths.

Pennsylvania: Allentown, Feb. 1-8, 1 case; Norristown, Feb. 8-15, 2 cases, 2 deaths; Philadelphia, Feb. 8-15, 74 cases, 19 deaths; Pittsburg, Feb. 12, 1 case; Reading, Feb. 10-17, 2 cases; Scranton, Feb. 1-15, 2 cases; Williamsport, Feb. 8-16, 5 cases.

Rhode Island: Providence, Feb. 8-15, 1 case, 1 death.

South Carolina: Charleston, Feb. 8-15, 3 cases.

Tennessee: Feb. 8-15, Memphis, 12 cases; Nashville, 1 case.

Texas: Houston, Feb. 1-15, 24 cases, 1 death.

Washington: Spokane, Feb. 1-8, 20 cases; Tacoma, Feb. 1-8, 4 cases.

Wisconsin: Fond du Lac, Feb. 8-15, 2 cases; Green Bay, Feb. 9-16, 16 cases, 1 death.

#### SMALLPOX—FOREIGN.

Austria: Prague, Jan. 18-25, 15 cases.

Belgium: Ghent, Jan. 25-Feb. 1, 2 deaths.

Canada: Winnipeg, Feb. 1-8, 4 cases.

Colombia: Cartagena, Jan. 27-Feb. 2, 3 deaths; Panama, Feb. 1-10, 50 cases.

France: Paris, Jan. 18-Feb. 1, 11 deaths.

Great Britain: Dundee, Jan. 25-Feb. 1, 1 case; Glasgow, Jan. 31-Feb. 7, 13 cases, 1 death; Liverpool, Jan. 25-Feb. 1, 3 cases; London, Jan. 18-Feb. 1, 2006 cases, 90 deaths.

India: Bombay, Jan. 7-14, 1 death; Calcutta, Jan. 4-11, 3 deaths; Karachi, Jan. 5-12, 13 cases, 1 death; Madras, Dec. 28-Feb. 3, 2 deaths.

Italy: Naples, Jan. 25-Feb. 1, 5 cases.

Mexico: City of Mexico, Jan. 26-Feb. 2, 1 case.

#### YELLOW FEVER.

Mexico: Vera Cruz, Feb. 1-8, 4 cases, 4 deaths.

#### CHOLERA.

India: Bombay, Jan. 7-14, 1 death; Calcutta, Jan. 4-11, 31 deaths; Madras, Dec. 28-Jan. 3, 4 deaths.

#### PLAGUE.

China: Hongkong, Dec. 28-Jan. 11, 1 case, 1 death.

India: Bombay, Jan. 7-14, 250 deaths; Calcutta, Jan. 4-11, 36 deaths; Karachi, Jan. 5-12, 24 cases, 23 deaths.

## Address.

### MEDICAL EDUCATION.\*

JOHN B. DEEVER, M.D.

PHILADELPHIA.

The choice of a subject to present on this occasion can not help but be a matter of considerable anxiety. When I received the invitation from my distinguished friend, your, yes, our, eminent Murphy, to speak to you, two thoughts were most prominent in my mind: First, one of pleasure at the honor bestowed upon me in being invited to journey so far to address an audience composed of many of the leaders in the American medical profession—which the majestic distances of this great country have prevented me from knowing personally as well as I know them by the luster of their names and achievements. The second thought that instantly followed was the difficulty of choosing a subject which would prove of sufficient interest and value to merit your kind invitation.

After reflection, it seemed clear to me that on an occasion like this no subject could be more suitable than that of Medical Education. A subject that will never become trite so long as the human race endures, for as one by one the great reaper, Time, mows down with his scythe the medical profession of to-day, it can leave no better legacy to posterity than the proper preparation of those who are to spring up to take its place.

There is one fact that makes this subject of the greatest difficulty. The fact that we are all medical students from the day we first enter the halls of our particular alma mater until, in the fulness of time, we must turn over our incomplete tasks to those who are to follow us. In this arises the greatest difficulty in arranging a course of study and deciding how far it should go before the student is fitted to advance from his medical school to the broader and higher school of a practitioner of medicine.

It is not in the province of this paper to discuss the theoretical question of a complete medical education. Indeed, the allotted span of life is too short for any of us to ever hope to explore the whole broad field open to us; but our aim is only to outline some of the principles, applicable to proper instruction in the first school of medicine which will enable its graduates to enter the higher school, fitted, both to advance the most rapidly and more important, with the greatest benefit to humanity, whose health and safety it is our noble mission to promote. The aim of a medical school should be to turn out men well grounded in the fundamentals of

medicine, who are ready to take up any of the many branches of the profession, into which their varying talents may lead them, and, above all, make them safe, conservative physicians with confidence in their groundwork, and enthusiasm to follow this forward and fill out their knowledge in the broader school to limits bounded only by the years Providence vouchsafes them.

In the halls of my particular alma mater hangs the portrait of Gibson, one of the master minds in the history of American surgery, and one of whom the Philadelphia profession may well be proud. Under his portrait are written these words, "Principles. Principles. Principles," and it were well that these words were engraven on the minds of all teachers of medicine. For it is only by the ingrounding of the principles of medicine that the young physician can judge between the false and the true, that he is sure to meet with in after-life.

The course of study in a medical school should be well balanced and proportionate, and this aim should be kept in mind. The time given is too short to fit a man to become a specialist, but is only sufficient for a groundwork that will permit him to follow his bent, either in post-graduate schools, or in that larger and greater school of personal experience in the daily routine of practice.

Even a rapid review of the curricula of the various medical schools will show that in most this balance is not maintained. Some devote too much time to laboratory methods, some to surgery and anatomy, and in others the preference is given to internal medicine. This unevenness is usually due to the domination of one branch of the faculty over the others, and suggests the remedy of each department asking for only the necessary time for the groundwork principles of their branch, and not that necessary for the instruction of future specialists. A college course should be practical; for instance, in some schools nearly as much time is given to instruction in chemistry as is given to anatomy, and yet the graduate is hardly able to examine a specimen of urine for albumin with certainty and dispatch. In every school of medicine, as in other lines of higher education, a well-organized body of alumni should be actively engaged in shaping the destinies and policies of their alma mater. Who is better prepared to know the actual needs and medical attainments which are necessary to the well-being of the young idea in medicine, and the needs of the ailing community, than he, who of long experience at the bedside and operating table has learned the many difficulties which the physician must overcome in treating disease; aye, he must do more than treat disease, he must treat the individual. If the time demanded is too long, let each course be cut down in proportion; but the

\* Address at Formal Opening of the Mercy Hospital Operating Amphitheater Under the Auspices of the Chicago Medical Society and the Northwestern University, Feb. 12, 1902.

pruning must be most judiciously done in those branches in which all medicine centers, anatomy, physiology and pathology.

Clinical and didactic teaching each have their place. Were it possible, the ideal method would be a presentation clinically, in a logical order, of all the varieties and stages of disease, but this is manifestly impossible, and didactic teaching must always fill up the gaps left by clinical teaching, and be useful in reducing the lessons learned clinically to a systematic and rememberable classification. Thus both kinds of teaching have their place; but there is little doubt that a lesson learned at the bedside, or operating table, is more real and applicable to the student than a lesson learned from a didactic lecture.

In this regard we may speak of the value of encouraging students to attend clinics outside of their particular college hospital. No one man has a monopoly of medical skill and much valuable information may be learned by the student, both of methods of thought and technique, outside of the walls of his alma mater.

A spirit of commercialism is one of the greatest enemies of a medical school. A large production at a cheap rate may be a good enough aim for a business house, but this spirit is fatal to a medical school. Too many schools seem to take pride in their large enrolment of students, forgetting that at the same time the teachers and clinical material are entirely inadequate for the proper instruction of so large a body of men. Salaries are in many cases insufficient. It is not reasonable to suppose that a man able to make a large income in practice will be willing to give up the best part of his time to a teaching position that pays him practically nothing. The primary object in selecting medical teachers should be the fitness of the individual for the position and not his price. A man of broad general education, with a large experience in the subject which he is to impart to the student, and who is recognized as an authority, with the ability to impart this knowledge, is the type of man who should fill the professional chair; not he who is possessed of influence or affluence sufficient to warrant an acceptance of a small or totally inadequate compensation.

In the great commercial organizations of to-day it is merit and fitness which is the accepted standard for leaders. Men who have demonstrated their peculiar ability in certain lines are chosen to lead; men who, of their own worth, command and receive yearly salaries that would be handsome endowments for any medical school or college. Why is it, therefore, that the men who are teaching those who will have the health of the community in the hollow of their hands, are compelled to accept a paltry pittance in return for the ability which is, as a matter of necessity and human limitation, a work of a lifetime to acquire? Can any one of you call to mind a physician or surgeon who has, from the practice of his profession alone, accumulated a fortune to compare with those of a thousand leaders in commercial life?

The inadequacy of salaries has in it one of two dangers: Either the chair is held by a man who holds his position only at its value as a means of advertisement for his practice, and who, therefore, as his practice increases, is compelled to give less and less time to it, until too often the only benefit the student receives from his occupancy is the luster of his name. Or, the chairs are held by men who have not attained that high plane of excellence, which I feel is so essential in those who

are to be leaders of men and who by virtue of their position are shaping the destinies of future generations. Either of these two alternatives is greatly to be deplored.

Nothing is of greater importance to the body politic than the proper instruction of those who are to have the care of the health of the community on their shoulders. The idea is preposterous that those to whom this instruction is intrusted should be men of mediocrity, either failures, or those whose measure of the value of the position lies in its value as an advertisement.

There is not, and never has been, a higher calling than that of a teacher, and a teacher of medicine is one of the highest in this calling. The dignity of the calling is seriously debased by its being occupied by men who, in order to obtain even a respectable livelihood, must make their high position subservient to their practice.

Many states and individuals have been liberal in their donation to this work, and surely nothing is more deserving of aid, and no charity will better repay posterity than one that assists in medical education or medical research.

This problem of education is a great and interesting one, and although it is still not entirely solved, yet in this regard we have many causes for congratulation on account of advances made and a fresh interest excited, not only among the medical profession but also among the laity.

The very occasion upon which we are gathered together, the opening of this beautiful amphitheater, shows the spirit in which education should be held. Beautiful as it is it is none too beautiful for the high purpose for which it is designed. The day of straight-backed, uncomfortable benches, foul smelling, badly ventilated amphitheaters has gone for good, and in its place has come such a room as it is our pleasure and delight to occupy this evening. A regard for health and comfort and artistic beauty coupled with a strict regard for the preserving laws of asepsis are here most faithfully carried out, independent of expense, time and trouble, and I venture to prophesy that the work that will be performed here by my illustrious colleagues will not be surpassed by any in this great home of modern surgery, the United States of America.

But, allow me to return to a consideration of those principles that are the rock upon which the enduring edifice of medical education must be reared. They are three, as I have already said: anatomy, physiology and pathology. With a thorough practical working knowledge of this triumvirate all knowledge of medicine is possible of attainment.

Where is the surgeon who does not, each day of his life, call to his aid his knowledge of anatomy and pathology, or the physician who is not constantly in need of a knowledge of physiology and pathology in making the simplest diagnosis, or in performing the simplest operation of surgery.

It seems to me that there is a pressing necessity for a pathology that can not be learned in the laboratory, which for the want of a better name I will call living clinical pathology. I refer to the kind of information which is obtained by the study of pathologic processes in the living body, and particularly that which is alone seen at the operating table. I have but to remind you of the appearance of a diseased vermiform appendix immediately before it is amputated, and the markedly different appearance which it presents the instant it occupies the bottle waiting for its reception. Or, the appearance of the intestines before and after the libera-

tion of an obstruction. Those of us who are granted the privilege of this view of nature's work in diseased states, frequently occupy positions varying materially from those of our brothers who make their observations upon the shell of the individual, fortunate or unfortunate as the case may be, from whom the God-like principle, life, has departed.

What manner of a man is it who is so lost to conscience that he would dare to remove a goiter or mass of lymphatic glands from the neck; or a gallstone from the common duct; or a vermiform appendix from a confining wall; a carcinomatous uterus from the pelvis; or set a broken thigh, without an accurate knowledge of the anatomic relations of the involved area; or, in the case of the physician who would venture a diagnosis of phthisis pulmonalis; gastric carcinoma or ulcer; brain tumor, or in fact derangement of any organ of the body, unless he knew the normal function of that organ from which he could draw logical and scientific comparisons and deductions.

I say again, and with all the emphasis at my command, who is better prepared to teach these principles of medicine than the man who has acquired the knowledge by years of experience and has the ability to impart them? Teachers are born, not made; although it may transpire that many years go by before the fact dawns on the minds of the community, or that he is discovered by a small circle of friends and admirers who are possessed of sufficient acumen to recognize the inherent talent of an otherwise obscure leader.

It is this knowledge of men that marks the great educators who are thus fitted for occupancy of the highest seats in the institutions of higher education. It is not buildings or money, however necessary they may be, which mark the standard of an educational institution, but the man at the head and the corps of associated educators over whom it is his function to preside, and whose efforts towards advancement in knowledge he shall foster and guide, that make the only solid ground for reputation.

Among the pioneers of those who have done most for the advancement of medical education stands the name of one of the members of the Chicago profession. I refer to Dr. N. S. Davis, who as long ago as 1839 began a series of articles asking for improvement in our medical schools. Almost the first in the field, his conscientious and able efforts were finally crystallized into the American Medical Association.

Thus we see from its very inception the primary object of this great bond of unity between the most widely separated members of the American profession was the advancement of Medical Education. That its purpose has been productive of valuable results, there can be no question; and Dr. Davis has been able to see results worthy of the greatest congratulation in the advancement of the medical schools of the country.

Contrast this beautiful, modern, aseptic amphitheater with the dirty operating rooms of fifty years ago! Contrast this well-equipped hospital, where the poorest of patients may receive care that is in no way second to that received by the richest man in his palatial residence, with the hospitals known to our fathers! Contrast the medical course, of thirteen to sixteen weeks, of fifty years ago with our present medical course, and we certainly see the best causes for congratulation and wonder at the magnitude of the changes in only half a century!

Kingsley in "Westward Ho" drew attention to the fact that the tide of immigration was ever toward the

westward, and it would seem that medicine is following in the track of the westward tendency in the United States. It was not many years ago when the East held the palm of medical education; but to-day we of the East must bow to the progress of our Western brothers, whose achievements speak so loudly and who, with no uncertain voice or faltering hand, have taken a place in the front ranks of medical attainment, and have raised the banner of Æsculapius to the virgin winds of the great West.

### CASE OF BROWN-SEQUARD'S PARALYSIS.

FROM STAB IN THE CERVICAL REGION, WITH COMPLETE HEMIPLEGIA, CROSSED MONOPLEGIA AND CROSSED TOTAL HEMI-ANESTHESIA.

ARTHUR R. EDWARDS, M.D.

Professor of Principles and Practice of Medicine and Clinical Medicine, Northwestern University Medical School (Chicago Medical College); Attending Physician to Cook County, Wesley, St. Luke's, Mercy and Provident Hospitals; Consulting Physician to St. Anthony's Hospital, Etc.  
CHICAGO.

I am indebted for the full, accurate and careful history to Dr. Tiecken, lately senior of the Cook County Hospital resident staff.

The patient was admitted July 10, 1900, after having been stabbed twice in the neck by an Italian compatriot during an argument. He fell, lost consciousness and remembered nothing till his arrival at the hospital in an ambulance.

Previous history: No previous injury nor illness.

Family history is negative.

Personal history: Patient admitted a venereal sore, not followed, however, by secondaries, but denied gonorrhea, although some slight urethral discharge was noted. Smoked and drank moderately.

*Examination.*—Middle-aged, male, of short stature, well nourished, florid complexion and anxious expression; mind was usually clear but at times slightly delirious. Head and scalp were negative. There was no evidence of violence, no edema. Skull was negative; no evidence of fracture; no tenderness.

Neck: One inch to the right of the median line posteriorly there was a wound about three-quarters of an inch long closed by silk sutures, but not sealed; below the mastoid process on the right side another small wound was seen about one-half inch in length, apparently inflicted by a sharp pointed instrument, directed from behind forward and a little upward. Free hemorrhage occurred from both wounds. They were sealed after thorough cleansing with a cotton-ecollodion dressing. No other evidence of injury was found around head or neck and dry dressings were applied and the patient put to bed.

Face: No evidence of injury found. Eyes: No evidence of injury to the external eye. Pupils reacted to light and accommodation; were regular in outline, but the right was larger than the left. There was no paralysis of any ocular muscles; no ptosis or sinking of either eyeball. Ears: No evidence of injury to either the external or middle ear. No hemorrhage from either ear. Function not disturbed. Nose: No injury to external nares. No evidence of fracture nor contusion. Mouth: No evidence of injury; lips move equally; no paralysis. Tongue: Clean, movable in all directions. Readily protruded without lateral deviation; palate moved normally; fauces normal; uvula in median line; no difficulty in articulation nor deglutition. Larynx: There was no evidence of paralysis; both cords moved equally. Chest was large, well-formed and symmetrical; expansion of lungs very slight but equal in ordinary respiration; mensuration gave no difference in capacity or size; the respiration was mostly abdom-

inal in character, and irregular in rhythm. Palpation, percussion and auscultation negative. Respiratory sounds feeble and distant, although vesicular.

Abdomen: Large and slightly protuberant; inspection showed normal movement on respiration; on palpation nothing abnormal was found; liver just palpable below the costal arch; spleen not palpable; no tenderness nor rigidity found, except over the distended bladder. Cardio-vascular system: Apex beat was in the fifth interspace just below the left nipple; percussion, negative; auscultation, negative; arteries were somewhat sclerotic; veins negative. Genitalia: Slight phimosis with long prepuce. There was no external evidence of venereal disease, although patient recounted a genital sore two years ago. On passing finger along beneath urethra with gentle compression, a small amount of somewhat turbid secretion could be squeezed out, although patient denied any recent infection. No stricture was found; scrotum and testicles negative. Rectum: There were no hemorrhoids, no stricture, no prostatic enlargement.

Extremities: On admission some slight movement was noted in the right upper, and free movement was present in the right lower extremity. The left upper extremity was slightly rigid, but no motion was perceptible. Patient could not move it when asked, and said he could not move the fingers. No power was present in either of the upper extremities, and when patient was asked to squeeze the hand, he was unable to do so. The left lower extremity was completely paralyzed and rigid and no motion could be elicited by voluntary effort of patient. When tickling the sole of either foot involuntary muscular twitchings were noticed. On flexing the left lower extremity the patient complained of pain, but the limb could be rotated in every direction without great discomfort.

Articulations: There was no evidence of disease or injury to any of the joints. When pressure was applied to the spine, pain was elicited in the cervical region, especially marked in the region of the fourth and fifth spinous processes, at which site the punctured wound was located. On flexing the head on the shoulders and on rotating it from side to side, pain was also experienced.

Muscles: Myoidema fairly well marked, and when the biceps pectoralis major or triceps were struck or pinched, slight reaction was noticed, and this followed by muscular twitching (most marked in pectoral group). Muscle sense could not be elicited, as it was impossible to make patient thoroughly understand what was meant. Bones: There was no evidence of injury, no tenderness, no deformity. The Nervous System: Save for some occasional slight delirium, considerable excitement and loss of memory the psychical functions were normal, the patient answering questions intelligently. The special senses were in no wise disturbed.

Sensation: Tactile sensation was lost upon the right side, especially in the arm and leg; while upon the trunk the anesthesia did not quite reach the median line. On the face and upper neck no change was noted. Analgesia was absolute upon the right side, as was temperature perception of both heat and cold. On the side of the hemiplegia there was no particularly marked hyperesthesia, save for pain on movement of the arm and leg and extreme sensitiveness of the soles of the feet, tickling of which caused the patient to cry out. The hyperesthetic zone, which often surmounts the bilateral anesthesia, could not be demonstrated. There was no anesthesia of any variety upon the left side, save for small, totally anesthetic, irregular patches over the left shoulder both before and behind it. Regarding muscle sensibility we can make no positive statement, since the patient failed to understand the test.

Reflexes: The corneal reflexes were active. The cremasteric, abdominal and mammillary reflexes were abolished on both sides. The right knee-jerk was normal, while the left was much exaggerated. The left patellar reflex disappeared in twelve hours and did not return for two weeks. The reflexes in the left arm were certainly exaggerated.

On admission to the hospital, July 7, 1900, the temperature was 99 F., the pulse 90 and the respiration 24. Retention of urine existed with negative uranalysis. For four days consti-

pation was absolute, when magnesium sulphate finally produced four bowel movements, after which involuntary evacuations of the urine and stools were constant for eighteen days. In three days after the left knee-jerk appeared, it was pronounced and a few days later was distinctly exaggerated. The patient was somewhat noisy and slept but little, whereupon chloral and sodium bromid were administered. Five days after admission he complained of headache and pain in the neck. The abdomen became painful and somewhat distended and the temperature rose to 102.6, and 103.4 was registered on July 16, 1900, six days after entrance. The dressings were removed and redness and edema were noticed about the larger wound. On opening it, after antiseptic precautions, a small amount of bloody fluid exuded. The parts were cleaned and a grooved director introduced without force along the wound tract, passing without resistance to a distance of 4.5 cm. when about 4 c.c. of a clear fluid gushed away. The wound was then dressed and the temperature fell to normal. Seventeen days after entrance some motion appeared in the right arm, but movement in the left arm and leg was possible only by movement of the shoulder and pelvis.

The patient's condition regarding the motor and sensory findings was as follows: In June, 1901, nearly a year after the injury, the hyperesthesia on the left side had disappeared, while the anesthesia on the right side was but little altered, tactile sensation now being fairly normal. The left-sided deep reflexes were exaggerated and the limbs more or less spastic and yet but little if any atrophy was present.

The case was clearly a Brown-Séquard paralysis, as discovered by Séquard and Turck simultaneously in 1850. According to Brown-Séquard's original proposition, on the side of the cervical section occur: 1. Paralysis of voluntary motion, muscle sensibility and vasomotor fibers. 2. Hyperesthesia of trunk and limbs, to touch, pain, heat, cold, etc. 3. Vasomotor paralysis of face and eyes (higher temperature, narrow pupils, moderate contracture of certain facial muscles). On the contra-lateral side: 4. Anesthesia for all varieties of sensation, except muscle sensibility.

I. Regarding the symptoms in detail, exact hemisection of the cervical cord produces a spinal hemiplegia on the side of the section, but, in clinical injuries as well as in experimental section, the trauma is rarely either wholly complete or strictly unilateral. In our case, the crossed paralysis of the arm is suggestive. Of speculative interest are the following possibilities, invoked in explanation of this crossed paralysis: 1. It is quite possible that the point of the knife, plunged into the left half of the cord, may have been given a downward twist at the end of the stroke so that the point injured the anterior portion of the right half of the cord. 2. The local left-sided injury probably accompanied by hemorrhage, since hematomyelia is prone to occur in the lower cervical region, could have produced indirect pressure, in which action hemorrhage may be reinforced by lymph stasis. I consider this mechanism somewhat improbable in that the crossed paresis has never disappeared, since Cushing, Kahler, Schmaus and Enderlen, describing symptoms *par distance* produced by hemorrhage, lymph stasis and swelling, conclude that more or less complete recovery is common. 3. It is likely that the hemisection was associated with secondary myelitis, the late temperature, superficial thoracic breathing, condition of the reflexes, bladder and rectal functions indicating an expansion of the original lesion by hemorrhage or inflammation. 4. The spinal hemiplegia on the side of section is explained by the general non-decussation in the spine of the motor tracts which have already crossed in the medulla. In some cases a decussation of the uncrossed pyramidal tracts may occur

in the cord lower down than the usual crossing point in the medulla, as is known through Flechsig.<sup>9</sup> Thus we can conceive of a spinal hemiplegia with contra-lateral monoplegia, due entirely to unilateral lesion. In this instance myelitis is, however, the better explanation. Déjerine and Thomas,<sup>27</sup> as well as Russel, Mallus and Sherrington, have spoken of a third pyramidal tract, the "homolateral pyramidal" tract, which may explain restitution of the motor function, and Edinger also mentions a "reserve" innervation by which decussation of motor fibers occurs lower than the pyramidal decussation in the medulla. Gowers<sup>2</sup> speaks of loss of power<sup>3</sup> on the contra-lateral side due to bilateral injury or to damage of non-decussating or recussating fibers. The clinical type is most characteristic when the lesion is located in the mid-dorsal region, but in cervical section, or pathologic foci, paresis of the arm with paralysis of the leg is more usual, because the cervical motor tracts are, so to speak, less compact than they are in the lower cord. Hence paralysis is limited more frequently to a group of muscles than to the entire upper extremity. "Conversely, paralysis of the leg may be incomplete while the arm paralysis is complete, owing to the escape of fibers for the leg which cross lower down in the cord." (Gowers.)

The paralysis gradually decreases in some instances (Cushing's case) with surprising rapidity, and if the anterior cells are intact it gradually becomes simple weakness. The motor functions are restored more readily than the sensory, the reverse being true of the peripheral nerves. There is an inactivity atrophy of the muscles without abolition of faradic irritability and without reaction of degeneration. The paralysis may be spastic instead of flaccid (Vix,<sup>15</sup> Mann<sup>24</sup>). A facial paralysis was noted in a questionable case reported by Lanzoni. Respiration is rarely affected, imperfect movement of the chest never having occurred according to v. Leyden and Goldscheider,<sup>1</sup> although in one instance paralysis of half of the diaphragm occurred, and in three cases the abdominal muscles were paretic. Involvement of the thoracic and abdominal muscles is usually indicative of a bilateral lesion. Swelling and edema in the paralyzed members have been observed by Glaezer,<sup>38</sup> and swelling with pain in all the joints on the paralyzed side was observed before death by Allesandrini, masses of coagulated blood being found in the joints at autopsy. Viguès, Joffroy and Soloman<sup>11</sup> have observed synovitis in the knee-joint on the paralyzed side and acute decubitus, referable to anterior root section.

II. *The Deep reflexes* are absent according to Glaezer,<sup>38</sup> while Erb,<sup>11</sup> Schultz,<sup>40</sup> Revillout<sup>41</sup> found them exaggerated on the side of lesion. Inhibition of the reflexes occurs not only from the brain but also, according to Sternberg from the cord itself. Bastian,<sup>46</sup> in four cases of total transverse lesion of the lower cervical and upper dorsal cord, observed abolition of the tendon reflexes, where shock was eliminated. Bruns<sup>29</sup> examined anatomically a similar case where the lumbar spine was intact. As yet we have no wholly satisfactory explanation for such cases. Bastian and Jackson suggest that the lumbar centers are independent of the cerebellum. Von Leyden and Goldscheider<sup>1</sup> propose inhibition from lasting irritation. Bowlby found no tendon reflexes in eleven cases of complete destruction of the cord, while in three incomplete traumata they were increased. Gerhardt suggests that the brusqueness of the trauma may have some bearing, since the reflexes were preserved in

his case of gradual total destruction of the cord by compression. Cushing<sup>45</sup> in a case of spinal gunshot wound and hematomyelia describes disappearance of the deep reflexes on the side of injury after four days and gradual reappearance as the paralysis decreased. Cushing remarks upon the dearth of references upon this sequence of reflex activity (ref. 46 to 50 inclusive) and quotes Kocher's case in which the weakened reflexes disappeared on the seventh day to return on the eleventh and were greatly exaggerated on the fourteenth. In our case the patellar reflex on the side of injury was first exaggerated, then, after twelve hours, disappeared for 14 days to finally return and remain exaggerated. In Cushing's case, the lesion was not strictly unilateral, there being more than the usual anesthetic zone on the side of paralysis, a temporary paralysis of the opposite arm, involvement of the bladder and rectum, bilateral intercostal and abdominal paralysis, etc. The skin reflexes are abolished or decreased on the side of paralysis and on the opposite anesthetic side they have been variously described as normal, weak, absent or increased.

III. *Hyperesthesia*, observed by Fodera in 1823 and Schoeps in 1827, occurs on the paralyzed side and also as a zone above the anesthetic areas near the level of the lesion. If the lesion be cervical both the anesthetic and hyperesthetic areas above are not zonular but irregular in contour. The same is observed in lumbar lesions. Hyperesthesia has been referred to the wound itself or to paralysis of inhibition. Irritation is not causal of anesthesia and hyperesthesia, according to Gowers, since both have endured twenty years or more. Gowers suggests that they "are due to an altered action of the cerebral centers on the opposite side of the brain." Hyperesthesia concerns tactile pain, heat and cold sensations and its absence infers incomplete section (Kocher). Kocher<sup>13</sup> observed such over-sensitiveness that mere movement caused the greatest pain. Hyperesthesia may, according to the same observer, develop later from secondary myelitis. Hyperesthesia was not found by Ferrier, Marshall and Bottazzi in experimental hemisection. It usually disappears rapidly, though its occasional protracted duration has been noted (v. s.). According to the investigation of Woroschiloff, W. Koch, and Martin, the fibers whose section results in hemianesthesia, lie in the lateral tract near the cerebellar and pyramidal tracts.

IV. *The zonular anesthesia on the side of injury and motor paralysis* is susceptible of ready explanation since the lesion involves not only sensory fibers which, we may say, are about to decussate to the other side and produce the crossed hemianesthesia, but also implicates sensory fibers from the contralateral side which may be said to have just decussated to the side of section.

V. *Muscle Sensation*: Abolition of muscle sense on the side of lesion is fully in accord with the conceptions of Erb, Bernhardt, Brown-Séquard, Fieber, Lanzoni and Allesandrini regarding the uncrossed course of muscle sense fibers. In Vix's case, with the preservation of locality sense, there was loss of pressure sense. Ataxia, observed by Bottazzi, Herhold<sup>23</sup> and Kocher, may be explained by abolition of the muscle sense (Leyden). Bottazzi<sup>19</sup> and Marshall<sup>18</sup> decided that the muscle sense was abolished in animals on the side of section, while Turner<sup>17</sup> and Ferrier<sup>20</sup> observed its loss on the side opposite to the lesion. The muscle sense fibers, and probably also those of pressure sense, run in the cord without decussation and most likely in the posterior tracts, i. e., in Burdach's column tending to enter

Goll's column higher up in the cord (Edinger, von Leyden and Goldscheider, Mott and Kocher). The column of Clarke, Gower's fasciculus and the lateral cerebellar tract are also suggested as likely paths for the muscle sense. Brown-Séquard's assertion that muscle sense is preserved on the side opposite to the lesion has been corroborated by Sachs, Freud, etc.

VI. *Vasomotor paralysis* on the intact side has been noted by Erb and Alessandrini, but the vasomotor symptoms usually lie on the side of section. The vasomotor fibers course in the antero-lateral columns, enter the anterior gray matter and leave by the anterior roots. Of vasomotor symptoms only relative narrowing of the left pupil was observed in our case.

VII. *Contralateral Hemianesthesia*: Brown-Séquard's doctrine regarding sensory spinal decussation was widely opposed and he finally abandoned his original conception and explained contra-lateral hemianesthesia as an irritative inhibition on the sensory paths, advancing as proof the following facts: 1, that section of the posterior roots of the upper dorsal region produce hyperesthesia of the limb on the same and anesthesia on the opposite side; 2, that a contra-lateral anesthesia produced by cervical hemisection can be converted into hyperesthesia by a second dorsal hemisection, while the hyperesthesia on the same side becomes anesthesia; and 3, that the anesthesia disappears when the corresponding sciatic nerve is moderately stretched. Brown-Séquard held to the clinical type of hemisection despite his altered conception of its etiology. Many physiologists maintain that the sensory fibers do not decussate within the cord; nevertheless clinical evidence in favor of decussation is very convincing. According to Gowers, "unilateral lesions of the cord cause loss of sensibility in all its forms on the side opposite to the lesion, proving beyond all doubt the decussation in the cord of the nerves of pain, touch and temperature. The paths of pain and touch sensation do not seem to be near together. Sensibility to pain has been lost in almost all the recorded cases, but that to touch is only two-thirds. The facts suggest secondly that the two paths for tactile sensibility are nearer together than are the two paths for common sensibility." "In no case of chiefly unilateral lesion has sensibility to pain been lost on both sides, whereas in two recorded cases sensibility to pain was lost on the side opposite to the lesion while that to touch was lost on both sides. Both these conclusions harmonize with the suggestion of experiment, that painful sensations are conducted in the antero-lateral column, those of touch in the posterior column."<sup>23</sup>

"Sensation is affected on the opposite side, but not quite up to the level of the lesion, because the decussation of the sensory tract is not immediate, but occurs somewhat above the entrance of the nerve."

"The upper level may vary for different forms of sensibility, in consequence probably of the level of crossing (in relation to entrance) being different for the several paths."

"A lesion in one side of the lumbar enlargement often affects sensation on the same side as motion, because it damages the sensory path before it has crossed. Experiments with animals often give uncertain results."

"Sensibility to pain is almost invariably impaired. The temperature sense is usually affected with that for pain. In only 2 of 20 carefully recorded cases was the sense of temperature normal and that of pain impaired, and in neither of these cases was the sensibility to pain

actually lost. On the other hand, in one-third of the cases, tactile sensibility was unaffected, and in about one-tenth it was impaired on both sides."

In Turner's<sup>17</sup> analysis, pressure (tactile) sensation was preserved on the paralyzed side in all the cases, though Mott refers to reduction of the same in certain cases, and in the majority of cases hyperesthesia (hyperalgesia) was found on the paralyzed side, and on the opposite side anesthesia for all qualities of sensation existed. Partial anesthesia has also been described, e. g., normal tactile sensation with incomplete analgesia reduction in tactile sensitiveness with analgesia and thermo-anesthesia or reduction in pressure or pain perception with thermo-anesthesia (v. Leyden and Goldscheider<sup>1</sup>). Fieber observed three times that heat sensation remained normal while electro-sensibility was lost. Regarding the opposite-sided anesthesia, Kocher describes it as complete or incomplete, as simple reduction in pain perception, usually with thermo-anesthesia. The anesthesia gradually regresses, and pain sensation may return before tactile sensation, which latter may anticipate the return of temperature sensation. Heat perception may return before cold is recognized (Kocher and Rosenthal<sup>25</sup>). Crossed anesthesia was absent in the experimental observations of Schiff, Mott, Bottazzi and Marshall, who found sensation reduced on the side of injury. The original statement that crossed hemianesthesia is complete has no universal application. Müller<sup>4</sup> observed in a case of solitary tubercle of the cord no complete crossed hemianesthesia but a selective hemianesthesia, hemianalgesia and hemithermoanesthesia. Mann<sup>24</sup> reviewed the literature of 102 cases of spinal hemiplegia with a view of ascertaining whether partial crossed anesthesia occurred in spinal mono- or hemiplegia, with the result earlier observed by Gowers and Oppenheim that, after rejecting 50 imperfectly reported cases, 31 cases presented complete anesthesia, while 21 cases exhibited the syringomyelic sensory dissociation, i. e., analgesia and thermo-anesthesia. He found no instance in which pain sensation was preserved, while the tactile sensation was disturbed. According to Mann's conception, there are probably not wholly distinct paths for each species of sensation and tactile sensation is possibly the fundamental or coarser element in all kinds of sensation, and hence it may persist when the finer sensations, differing from tactile less in quality than degree, have disappeared. Grasset,<sup>28</sup> in speaking of *dissociation syringomyélique des sensibilités*, asserts: 1, that syringomyelia may exist without sensory dissociation, and 2, that dissociation occurs in other diseases, e. g., neuritis and myelitis (Gombault, Lanteraux and Reboul), hysteria (Charcot), sciatica (Ziehl), lepra (Leloir, Jacoby, Babinski, Thibierge), tabes (Parmentier), hematomyelia (Minor), sclerosis multiplex (Freund), spinal syphilis (Brissaud, Hanot, Déjerine, Thomas, Prat, Cestan, Meunier), intramedullary tumor (Gendrin), or meningeal tumors (Charcot, Gindrac, Oré), multiple tumors (Bruns,<sup>29</sup> Schlesinger), with the Brown-Séquard syndrome (Max Laehr, Müller, Charcot, Gombault, Gowers, Beavor, Steele and Williamson), spinal compression (Van Gehuchten), complete transverse spinal lesion (Minor<sup>30</sup>), Edsall in Pott's disease, trauma of cord (James H. Lloyd), spinal concussion (Reynes<sup>51</sup>), etc.

Brissaud<sup>35</sup> and Raymond<sup>56</sup> speak of incomplete dissociated anesthesia. From the foregoing citations the inference is drawn that conduction of temperature sensation is closely associated with that of pain percep-

tion. In the contra-lateral dissociated (syringomyelic) hemianesthesia, Kocher considers that the tactile sensation tracts do not course with the other sensory fibers nor with the pyramidal motor fibers.

Non-decussating sensory fibers may be found in: 1, the posterior columns; 2, in Clarke's columns, and from its cells to the cerebellar and Gowers' fasciculi, and 3, in the "Grenzgebiet" (Endinger), the posterior mesial portion of the lateral tract. This last-named tract is concerned with tactile sensation (though perhaps not with the finer sense of locality), as demonstrated by the experiments of Koch, Woroschiloff, and Martinotti in which hyperesthesia follows their section. The question is as yet undecided whether finer touch sensations as localized pressure sense are conducted in the posterior column near the tracts of muscle sense. An isolated conduction of simple tactile sensation in the posterior columns seems improbable to Kocher and is likely confined to the lateral column. Kocher concludes that tactile and pain sensations are conducted in the lateral column, but in no unilateral manner, and that many of the fibers of the posterior root sooner or later cross through the anterior commissure to the other side of the cord, conducting the bulk of the sensory fibers and certainly those of pain and temperature sense. Analgesia, often observed as the single contra-lateral sensory variation in (partial) hemisection, has been produced in animals by Holzheimer<sup>26</sup> by section of the lateral tracts and by section of the posterior half of the cord to a point a little anterior to the pyramidal tract. The later experiments of Brown-Séquard (q. v.) must perhaps be explained by a double collateral crossing of the sensory fibers.

Priapism, vesical and rectal disturbance may be wholly absent or occur transitorily, possibly as evidence (Kocher, Cushing), of some injury to both sides of the cord. Delirium does not explain the bladder and rectal disturbance in our case since they outlived the delirium.

Radiate pains, observed by Vix, Berndt and Albanese, and spastic paralysis seem to Kocher to indicate an incomplete lesion, favoring the production of irritative symptoms. In one instance spasticity and partial loss of power occurred on one side with formication and anesthesia on the opposite side. In another instance, contractions occurred as paralysis decreased while radiating pains followed the hyperesthesia.

*Prognosis.*—In clinical and experimental cases, almost complete restitution to normal is possible (Vix,<sup>15</sup> Kocher<sup>13</sup>), and it is not due to re-establishment of conduction in the severed tracts, since ascending and descending degeneration occurs, nor to simple cord contusion (Schrader<sup>16</sup>), but rather to assumption of the functions of the divided fibers by the uninjured side of the cord (Kocher). The immediate prognosis of hematomyelia is usually good (Cushing) while J. K. Mitchell warns against an absolutely favorable late prognosis, since tardy sclerotic changes may result even when immediate recovery seems perfect. The prognosis of Brown-Séquard's paralysis necessarily varies according to the etiology of the syndrome, e. g., syphilis, tumors, sclerosis, myelitis, tuberculosis or trauma, hematomyelia, fracture, luxation, etc.

#### GENERAL CONCLUSIONS.

1. The lack of correspondence between hemispinal section in certain lower animals and in man is probably due to different anatomico-physiologic conditions.
2. The Brown-Séquard clinical syndrome undoubtedly

exists, although less an entity than a symptom and exists despite some physiologic evidence to the contrary.

3. Variations from the original type occur from the character of the numerous etiologic factors and from the frequency with which experimental and clinical lesions affect more or less than one exact half of the cord.

#### PARTICULAR OBSERVATIONS.

4. No primary elevation of temperature from cervical injury was observed, the secondary elevation being probably due to subsequent myelitis.

5. Few vasomotor symptoms were observed.

6. The Brown-Séquard paralysis was typical in the sense of the original description since the contra-lateral anesthesia was not dissociated but total, i. e., "for all varieties of sensation."

7. It was atypical in the bilateral lesion, the crossed and persistent monoplegia, the shallow respiration and bladder and rectal disturbance.

8. The failure of the right side to assume the functions of the severed right half of the cord seems to indicate a bilateral lesion.

9. Again, notwithstanding the bilateral involvement, the homolateral anesthesia was slight, arguing for involvement of the left side chiefly.

10. According to Kocher, spasticity speaks for incomplete lesion favoring irritation, yet the persistence and fulness of the symptoms in this case speak against partial lesion.

11. The zone (or plaque, in case of cervical section) of surmounting hyperesthesia was lacking, possibly explained by the mental state (?).

12. The condition of the deep reflexes on the side of lesion is somewhat unique in this case. The left knee-jerk was first exaggerated, then in twelve hours disappeared, was absent for fourteen days, and in three days after reappearance became much exaggerated, whereas the arm reflexes from first to last were exaggerated.

13. An interesting, though perhaps wholly accidental, connection existed between the absence of the knee-jerk and the presence of involuntary evacuations, which ceased about the time the patellar reflex returned.

14. The evacuation by the grooved director of what was probably cerebrospinal fluid is interesting and especially the direct subsidence of the fever, delirium, etc. Unfortunately, a bacteriologic examination was prevented by the sudden gushing out of the fluid in this species of spinal puncture.

15. While the clarity of the fluid did not speak against intramedullary hemorrhage (hemato-myelia), still the fever, the persistence of the symptoms and possibly the evacuations of the fluid seem to me to indicate an acute secondary (meningeo) myelitis.

16. The prognostic lesson from our case is obvious. While at first the outlook was no worse than, e. g., in Cushing's case of probable hemato-myelia, and while general observation warrants a relatively favorable prospect, yet recapitulation of the clinical course, the delirium, pain in the head and neck with the fever probably indicated the late myelitis with its usual prognostic inferences.

## DERMATOMYCOSES IN THEIR RELATION TO ALLEN'S IODIN TEST.

JACOB SOBEL, M.D.

DERMATOLOGICAL ASSISTANT AT THE GOOD SAMARITAN DISPENSARY, NEW YORK CITY.

Parasitic diseases of the skin may be classified into: 1, those in which the definite etiologic factor has been isolated and identified (microsporon furfur of tinea versicolor, the trichophyton of tinea tonsurans and circinata, and the achorion Schoenleinii of favus), and 2, those in which *no absolute* proof has been given of the constant presence of vegetable micro-organisms, and yet which in appearance, clinical course, reaction to anti-parasitocides, and other circumstances, seem to be of parasitic nature (pityriasis rosea, eczema marginatum, mycotic eczema, etc.).

In this paper it is my purpose to deal only with the following conditions: pityriasis versicolor, pityriasis rosea, tinea circinata (localized and disseminated), eczema marginatum and mycotic eczema, and endeavor to show that while in most cases these admit of ready diagnosis there are times when differentiation from other important conditions must be made. No one test in my experience for the determination of the parasitic nature of these affections, apart from the actual demonstration of the fungus, has served me so well as the one which forms the subject of this paper.

Pityriasis versicolor, or chromophytosis, is a condition which, as a rule, is within the diagnostic abilities of all and yet there are some points about it that are often overlooked. Almost without exception text-books state

that this disease affects the covered parts of the body and leaves the parts exposed to light—face, neck, and more particularly the palms—perfectly free. This statement is certainly not true, as I have had ample opportunity of convincing myself, more especially since the iodine test was brought to my notice by Dr. Charles W. Allen, of New York City.

This test consists in applying to the diseased areas, or to suspected ones, a solution of iodine, preferably Lugol's solution (iodi, 5; potass. iodidi, 10; aquæ, 100). In the diseased regions an intense dark-brown or deep mahogany discoloration takes place at once, which shows itself in marked contrast to the surrounding healthy tissue, which latter stains a very light-yellowish color. If the lesions are small and punctate, as they are at the onset of the disease, the discoloration will appear as such; if diffuse and confluent there will be a large darkened patch. The intensity of the reaction, i. e., the depth of its color, will depend upon the stage and severity of the disease; at the very outset, or in the retrogressive stage when the infection is slight, the stain will appear lighter than in the more active stages of the disease, though far more intense than in the normal skin.

It is thus seen that not only is the test of value for the recognition of small, faint and suspected areas of disease, but that it also gives us information as to its course.

With the aid of this test I have time and again been able to demonstrate the existence of lesions on the neck, at the angle of the jaw, on the chin, on the forehead, and on the side of the face up to the roots of the hair. In some instances the lesions were so faint as to be hardly perceptible to the naked eye, and yet an application of Lugol's solution brought them into relief.

In applying the test it is well to make a cotton swab tightly twisted on the end of a tooth-pick, applicator, or match, and then to rub in the Lugol's solution over any given area; in this way the contrast between the darkened patches and the healthy skin is more clearly brought out.

In subjects with hypertrichosis of the chest and abdomen, lesions of tinea versicolor, perhaps more so than in any other affection, are easily overlooked; under such circumstances Lugol's solution is of great service in making distinctly visible many otherwise imperceptible lesions. Some patients present themselves just after a bath with a pale-pink eruption which proves very puzzling. The application of Lugol's solution not only stains these areas but corroborates the diagnosis of tinea versicolor by the general configuration of the patches.

Gottheil has reported a unique case of palmar chromophytosis, thus disproving the former ideas as to the non-involvement of this part. Only recently<sup>1</sup> the same author has published a most exceptional case of pityriasis versicolor of the face alone in a young colored man.

It is commonly known that recurrences, if I might use that term, are quite frequent in this affection, being caused by the failure to eradicate the disease in its entirety. Yet, there are instances in which, so far as the human eye can determine, the disease has been eradicated, or controlled, and still relapses occur. How are we to explain these cases?

1. Recurrences are due to the overlooking, and consequent non-treatment, of a region which Dr. Allen has repeatedly shown to be one of the main causes of re-infection, namely, the suprapubic region. In men, as well as in women, small faint patches of the disease are

hidden in this region and are never treated because never suspected. In these cases the application of Lugol's solution renders the diagnosis doubly sure; for pale and hidden lesions at once become visible and lead the way to a proper eradication of the disease. As long as any vestige of the disease remains, so long will recurrences take place. Lesions in the suprapubic region appear at times to itch more than in other parts; this gives rise to scratching, and the subsequent conveyance to other regions, and to auto-inoculation. I do not say that the suprapubic region is affected in every case, but the number is sufficiently large to warrant attention. With Dr. Allen, and in my own experience, I have seen instances in which a history of numerous outbreaks was given, and where thorough treatment of the aforesaid region brought the disease to a standstill.

2. Recurrences are due to lack of proper treatment. It is the custom of most physicians to look very lightly upon the treatment of this condition, to give merely exfoliating medicaments of green soap, hyposulphite of soda, sulphur, etc., and to rely upon these, with an occasional bath, to control and cure the affection. This, however, is insufficient. In studying the development of the disease it will be seen that the incipient patches have their origin about the hair follicles and, in some cases, appear to extend into them. The origin of the patches being "perifollicular, or perhaps intrafollicular," penetrating agents, such as B-naphthol, resorcin, chrysarobin, etc., must be combined with desquamating ones in order to obtain the best and most permanent results.

3. A third and most important cause of recurrences is the improper care of the underwear during and after the course of the disease. So abundant are the spores in any given scraping that it is safe to assume that many of them cling to the underclothing, which, if not changed frequently and not properly and thoroughly boiled upon removal, will again inoculate the skin. If possible the underclothing should be changed daily during the course of treatment and re-used only after appropriate disinfection.

With this disease few conditions can be confounded; only three are worthy of note—chloasma and lentigo, syphilis, and dirt. It seems strange that dirt should be considered, and yet I have seen mistakes made both ways, as it were. I remember very well a case of pityriasis nigra shown by Dr. Allen before the New York Dermatological Society, in which "at first glance almost all the gentlemen present were disinclined to attribute to the disease any great share in producing the appearances." In fact, when seen at the dispensary, I myself first thought of a dirty neck. After the thorough use of soap and water the condition remained unchanged until "vigorous treatment with chrysarobin" freed him from the affection. Not only was the case unusual on account of its dark color, but there were patches of the disease extending on the right side of the face to the malar bone and on the left side to the roots of the hair. There were also several spots in the suprapubic region.

On the other hand, I have seen areas of dirt distributed on the neck, strongly suggestive of tinea versicolor; these responded very kindly to soap and water, but not to the iodine test.

Chloasma and lentigo are of course in and not on the skin; that is, they are pigmentations of the mucous and not the horny layer; they are not scaly and do not respond to the test. The fact that chloasma is more common on the face is not of positive value, since it has been shown that patches of chromophytosis are occasionally found in that locality.

Some writers have stated that syphilitic macules may be confounded with the disease. Not only is their color different, but they are not scaly nor elevated, nor do they respond to Lugol's solution. The presence of the microsporon furfur under the microscope is proof positive and easy of demonstration. In spite of all this I have known the conditions to be confounded.

In a number of instances I have observed tinea versicolor and a macular syphilid in the same patient. In these cases it is interesting to see how Lugol's solution selects, as it were, the parasitic areas and leaves the syphilitic ones faintly tinged at best.

As in a previous paper<sup>2</sup> on a similar subject, I would conclude:

1. The old theory that only hidden parts are affected is no longer tenable.

2. Allen's iodine test is of marked value, not only for classroom demonstration and for bringing into relief pale and hidden lesions, but also for differentiating parasitic, or seemingly parasitic, skin affections from those of a non-parasitic nature.

3. Recurrences are in the main due to the overlooking and non-treatment of the suprapubic region and to the use of desquamating agents to the exclusion of penetrating ones. Both must be combined if a cure is desired.

I have dealt somewhat at length with this condition, because it is a type of disease which best demonstrates the application of the test.

At this point I might say that in none of the conditions generally accepted as non-parasitic has the test been proved positive. Thus, I have applied it to seborrheal eczema, scaly syphilids, simple eczema, dermatitis, the desquamations of scarlet fever, measles, and other conditions of a desquamative nature; while the cast-off epithelium in these cases will take up the Lugol solution faintly, a little more I might say than perfectly normal skin or an erythematous patch; there is no deep mahogany or dark brown discoloration; that is, there is no positive reaction.

There have been a few rare cases of non-parasitic nature in which the application of Lugol's solution was followed by a suspiciously-looking mahogany discoloration. Within a few minutes, however, this wore off, thus differentiating it from the stain of parasitic diseases, which remains for a very much longer period of time.

Pityriasis rosea, or pityriasis maculata et circinata, is a condition which occurs more frequently than is generally supposed; it is usually either entirely overlooked or else diagnosed as something else. Contrary to the opinion of Crocker and Stephen Mackenzie, it is in my experience far more frequent in adults than in children, and this despite the fact that the material at my disposal embraces a very large number of the latter. It does occur in children, however, and within the past three years I have seen in all perhaps a dozen cases under 10 years of age; lately I observed an instance in a child of fourteen months.

It has been, and still is, a mooted question as to the exact etiology of the disease. The Vienna school is outspoken in its belief that it is parasitic in its nature; in fact, that it is but a form of disseminated ringworm, and hence the term *herpes tonsurans maculosus et squamosus*. They claim that many are not convinced of its mycotic nature on account of the great difficulty in finding the spores during the first few days of the dis-

ease. Basin considers it arthritic and Vidal claims to have found a *microsporen anomoeon*. I have heard Lassar state that the disease was due to a fungus generally found in new underclothing that had not been washed before wearing.

For my own part, I must confess that my search for mycelia and spores in this condition has not been productive of any results, and yet I have no hesitancy in stating my personal belief that the disease is parasitic, so markedly does it take up Lugol's solution.

In a few instances I have been able to obtain a history of the "mother patch," "primitive patch" or "herald patch," appearing on the limb a short time after wearing new stockings. A certain number of adults stated that it appeared after taking a bath; in these cases the probability of improper drying, and a favorable soil for the development of fungi, might be considered. In many instances patches were found on the face, an occurrence far more frequent than is generally supposed. There were months when no cases were observed and others when groups would appear. During the latter part of March and the early April of 1901 as many cases were observed as during the entire previous four months. Many of the patients complained of neither local nor general disturbances; in others there was intense itching and, in some children, a febrile movement, with headache, malaise, and coated tongue. One case was combined with purpura, but no connection between the two diseases could be traced. The advocates of the arthritic theory might advance this combination in favor of their views.

To all appearances the disease is not contagious; we have, however, noted the affection in one instance of a man and wife.

Should you apply Lugol's solution to these irregular or circular patches, with chamois-like wrinkled centers, the deep mahogany or dark brown discoloration appears. Here also the more recent and more active lesions take up the stain more deeply than the older and declining ones, thus giving us a guide to the course of the disease.

The diseases most frequently confounded with the condition are: (a) syphilis, (b) disseminated ringworm, and (c) eczema.

The uninitiated when brought face to face with pityriasis rosea almost invariably diagnose macular syphilid, more especially when there is no itching, when a number of the lesions are in the erythematous stage, and when they follow the course of the ribs as they so often do in pityriasis rosea, as well as in syphilis. Leaving aside all other differential aids—the history, presence of the primary lesion or its scar, adenopathy, alopecia, mucous patches, color, absence of scaling—the application of Lugol's solution and the obtaining of a deep mahogany discoloration would make me strongly suspicious of pityriasis rosea. Never in a macular syphilid has the test made by me been positive.

Syphilis, of course, offers no protection against the disease, so that a combination as reported by Allen<sup>3</sup> must be remembered. In this particular case—and I have seen it in others—the rosy patches were stained dark brown by Lugol's solution and the syphilitic roseola a faint yellow.

Eczema is frequently diagnosticated for pityriasis rosea. I have seen the error mainly committed in children, perhaps because we are most of us accustomed to associate the disease with adult life. In children it has been my experience that pityriasis rosea in many

instances is atypical in appearance, lacking for the most part the circular or elliptical form of patches with rose-colored border and wrinkled centers, and presenting more irregularly sized and shaped scaly areas. Here and there a typical patch will be seen, an important point in the diagnosis. In all of these cases Lugol's solution stains the lesion deep mahogany, or very dark brown, while in simple eczema a faint discoloration is seen at the best.

In adults, seborrheal eczema sometimes is a stumbling block in diagnosis. This affection, however, is in most instances associated with seborrhea of the head and face, involves, as a rule, the sternal and interscapular regions, presents more elevated, more greasy and more palpable lesions, has a darker border and thicker scales, and does not stain mahogany with Lugol's solution. Furthermore, this disease does not disappear spontaneously.

It is from disseminated ringworm that differentiation is so often necessary and so difficult, all the more so since the test is of no value here. In both conditions the reaction is positive, ringworm being positively and pityriasis rosea very probably of parasitic origin. The test then has its limitations, in so far as it can not differentiate one parasitic cutaneous disease from the other; it excites when positive a very marked suspicion of the parasitic nature of the disease under diagnosis. In fact, when any cutaneous lesion responds to this test it is to my mind strong presumptive evidence that it is parasitic, and is treated on that basis. This is, of course, an inference drawn from its action in diseases positively known as parasitic.

In differentiating pityriasis rosea from disseminated ringworm we must then look to other aids than the iodine test. If we find the trichophyton the diagnosis is of course assured. In its absence, however—and the detection of the fungus in disseminated ringworm is not always a simple matter—a history of other cases in the family must be sought. Contagion is common in ringworm and very uncommon, if it occurs at all, in pityriasis rosea. Pityriasis rosea occurs more suddenly, involves a greater portion of the body in a shorter space of time, is more irregular in shape and its border is not so marked, and never papular or papulo-vesicular.

The ordinary ringworm of the body, *tinea circinata*, as found on the face, neck, hands, etc., need not engage much of our attention. Suffice it, that this responds to Lugol's solution; the raised border, whether papulo-vesicular or crusty, appears deep mahogany, at times almost black, in marked contrast to the faintly tinged center. After successful treatment one can follow almost daily the diminution in intensity of the stain, until finally, at the time of cure, no reaction takes place.

Diagnosis of ringworm is usually a simple matter, but there is one condition with which I have seen it confounded; I refer to the circular form of contagious impetigo—*impetigo circinata*. There are some few cases of this condition in which the lesions closely resemble *tinea circinata*; they have a circular form, a raised edge, a healed center, and there may be a history of other cases in the family; they are differentiated by the fact that the edge is more friable and crustaceous, that there usually exist other lesions of contagious impetigo in association with *pediculosis capitis*, that the trichophyton is not found and that they do not take up Lugol's solution.

Eczema marginatum or trichophytosis cruris occurs where opposing skin surfaces are kept in contact for a long time, and is seen most frequently on the inner

surface of the thigh, buttocks, peri-anal region, axilla, and under surfaces of the breasts in women. When associated with the sharply defined border diagnosis is simple and is rendered more so by the fact that the edge stains mahogany with Lugol's. In other cases, especially on the thigh, there is no distinct border, but more of an irregular, broken line, with outlying patches of various shapes and sizes. It is in these doubtful instances that a response to Lugol's shows the similarity of this process to the ordinary eczema marginatum.

Though Kaposi, Köbner and Pick have demonstrated the presence of fungi in the epidermic scales, it is no easy matter to find the trichophyton, and for me the main guide in doubtful instances has been the appearance of a deep mahogany stain upon the application of Lugol's solution. Apart from being an aid to diagnosis the solution is an excellent method of treatment. As the condition improves the areas take up the color more faintly and finally not at all.

In mycotic eczema, which by its very name signifies a parasitic origin, this test appears to advantage. Despite the fact that absolute proof of its parasitic nature is wanting, in its configuration, obstinacy and response to Lugol, it follows the truly parasitic diseases so closely that it is safe to assume that subsequent observation will place it under that category.

In conclusion let me state that:

1. For teachers who give classroom demonstration, Allen's iodine test will serve to bring into greater prominence visible parasitic lesions and into view pale, hidden, and sometimes invisible ones.

2. A positive reaction to Lugol's solution in the form of a deep mahogany or dark brown discoloration is strong presumptive evidence that the lesion is parasitic. In the absence of absolute proof of the parasitic nature it is of the greatest aid and in the presence of a parasitic skin lesion, it serves to make assurance doubly sure.

3. It is not of service in differentiating one parasitic disease from the other; this must be accomplished by other clinical and microscopical data.

1828 Madison Avenue.

## THE ORIGIN OF CARCINOMA OF THE STOMACH FROM CHRONIC ROUND ULCER OF THE STOMACH.

G. FUETTERER, M.D.

Professor Diseases of Stomach and Liver, Chicago Poliklinik.  
CHICAGO.

Since I had seen a very instructive case of combination of carcinoma of the stomach and chronic round ulcer, in November, 1893, it has always seemed to me that the stomach is the organ most suited for the study of the origin and development of carcinoma.

The case referred to was observed clinically from 1893 to 1895, when the patient died, and the postmortem examination revealed, in the pyloric region, a large ulcer, the lower edge of which was carcinomatous, while the mucous membrane and the upper edge showed no carcinomatous degeneration whatsoever. The difference between the condition of the two edges of the ulcer was too striking to be ignored, and caused me to give further thought to the matter. It then occurred to me that only mechanical influences could explain the different conditions of the two edges of the ulcer. The mechanical factors coming here into play are, the irritation caused by the food and the contractions of the stomach, which force the food into certain directions. It can be easily

understood that the qualities of friction caused by the two factors named must have been very different on the upper and the lower margin of the ulcer, as the food would slip easily over the former, while on being forced toward the pylorus, hard rubbing of the lower margin would be caused by the contents of the stomach. Hard particles of food, such as crusts of bread and crisply fried meat on passing the precipice formed by the lower edge of the ulcer, must necessarily cause considerable irritation.

If our observations in this case as to the localization of the carcinoma are not merely accidental, if it can be shown that similar conditions are the rule, rather than the exception, then we are forced to admit that the mechanical factor is indeed one of the most prominent, if not the most prominent cause of carcinoma. It will, however, require much study to state with exactness which part of the margin of ulcers in different parts of the stomach are those most exposed to friction, as the different forms and sizes of ulcers, their localization, adhesions and dilatation of the organ and misplacements of the same, will have to be carefully considered in each individual case. In the pyloric region conditions are very simple, and we may take it for granted that as a rule the lower margin of the ulcer, which is on the pyloric side of the same, is most exposed to mechanical irritation, and should, therefore, as a rule, show the beginning of carcinoma; while the upper margin becomes involved very much later.

I shall now report the observations I have made since the year 1895, and shall also review the cases of combination of carcinoma and ulcer of the stomach found in literature, in reference to the question before us. In doing this, I shall only consider cases in which an operation or postmortem examination have shown that combination of carcinoma and chronic round ulcer of the stomach really existed. Some of the cases which I found in literature are a little doubtful, but the source of error is so small that I do not intend to eliminate them. It may be mentioned that my own cases came from my own clinical material and from a very limited postmortem practice, which allows the conclusion that carcinoma and ulcer of the stomach occur together much oftener than even those are willing to admit who, like Zenker, have long ceased to believe in the rarity of this condition.

It must be taken into consideration, furthermore, that all over the world comparatively few cases are examined postmortem, and because of this the frequency of the condition is not revealed. Clinically, we can not help but believe that the development of carcinoma very often follows in the wake of an ulcer, even though the material for observation is not large.

I shall now bring, as the first case, one of adeno-carcinoma of the stomach, which had developed from a very small, typical ulcer, measuring only one centimeter in diameter. Up to the observation of this case, I had always supposed that carcinoma developed only from larger ulcers and such as had existed for a long time. Therefore, whenever I had had occasion to diagnose a fresh ulcer of the stomach, I had made a good prognosis, not only as to a prompt healing, but also as to more remote consequences. This case has taught me to be very careful and to consider the possibility of the development of carcinoma in every ulcer as a danger not to be ignored. I now make two prognoses for round ulcer of the stomach: The immediate prognosis refers to the healing of the ulcer, the disappearing of the symptoms—

particularly the pains—the danger of hemorrhages and perforations; the more remote or late prognosis considers stenosis of the pylorus, consecutive dilatations of the stomach, etc., but particularly the very frequent complication with carcinoma. *The early prognosis of the round ulcer of the stomach is fairly good, the late prognosis is quite bad.*

CASE 1.—Mrs. G., 59 years of age, came from a healthy family, but a brother died at the age of 42 years, of carcinoma of the stomach. The patient herself, at the age of 23, had dull pains in the epigastrium, which commenced with vomiting, that occurred several times daily, and lasted three months. Every year similar attacks occurred, which lasted for two or three months; the last one continued, with interruptions, from June, 1899, up to the time of death of the patient, on Oct. 19, 1899. While the very anemic patient had been under my care in the summer of 1899, she was given the rest treatment, with the usual dieting, as is prescribed in cases of ulcer of the stomach. Her pains disappeared entirely, and after four weeks' treatment she was allowed to go home, being free from all symptoms. A month later, pains of a dull, gnawing character developed, becoming very intense and lasting as the case advanced. The patient became more anemic, and, as she had to be kept under the influence of morphin continually, operation was advised in the belief that a carcinoma was developing from the supposed ulcer. The operation was performed by Dr. Malcolm L. Harris, who removed a round piece of the wall of the stomach, having a diameter of 4 centimeters from the region of the lesser curvature, a little upward from its middle portion. On the outside of the dissected piece, inflammatory thickenings were found, which included a lymphatic gland of hemorrhagic condition. The very weak patient died after two days. The postmortem examination showed that the stomach wound had closed, there was no leakage and no infection. It should be mentioned that a large renal calculus was found in the pelvis of the left kidney.

Description of the Resected Piece of the Wall of the Stomach.—Observation of the inner surface of the resected piece showed in its center a circular defect, with a diameter of one centimeter a *very* small typical round ulcer surrounded by mucous membrane in a condition of chronic catarrh, and on one side, involving about one-third of the edge, two small, whitish nodules which together had a diameter of 1.2 centimeters, and which, as later microscopic examination revealed, represented an adeno-carcinoma. The illustration (Fig. 1) only shows one-half of the resected piece, as the other half was imbedded, stained and examined microscopically. Later, the half shown in the illustration was used for microscopic examination, so that all parts of the ulcer and the small growth have been well examined. Microscopically it was shown that the small, round defect was really a true open ulcer that had no tendency whatever to heal. The mucous membrane was strongly and uniformly infiltrated with round cells from which resulted a broadening of the intertubular spaces. The glands of the mucous membrane were much elongated, more or less tortuous, and their lumina, at the upper end, were dilated. Very high cylindric epithelial cells lined the glands, and their nuclei were rich in chromatin. The small growth itself showed similar changes of the intertubular tissues and also of the glands, only much more exaggerated. The glands were more tortuous, like corkscrews, their middle and deeper portions more dilated and lined by a high, cylindric epithelium, the nuclei of which were also very rich in chromatin. Towards the muscularis mucosæ, the interglandular, cellular infiltration increased, the position of the glandular tubulæ became more and more irregular, and here also dilatations of the glands and much branching of the tubules were found. Some of the tubules appeared filled

with epithelial cells, and they penetrated the muscularis mucosæ, growing into the submucosa and even into the muscularis, surrounded by an irregularly distributed round-cell infiltration. The lymphatic gland, which was found on the outside of the dissected piece, showed a hemorrhagic condition all through, but no metastases. The stomach itself, which was removed postmortem, showed the changes of chronic gastritis and a thickening of the muscularis along the suture; further ulcers or scars were not found.

This case is interesting for different reasons: 1. Because such a small ulcer was found complicated with carcinoma. 2. Because we can not very well say that this ulcer was a product of the carcinoma, as it still showed all the characteristics of the typical round ulcer of the stomach, and as the new formation had only involved a small part of its edge. 3. Clinically, this case is of very great importance, as it shows that the disappearing of the symptoms of ulcer of the stomach during a rest cure, will not permit of our concluding positively that the ulcer has healed. It will be remembered from the history that all the symptoms had disappeared during the rest cure, and yet we have found that the ulcer showed no visible tendency to heal, even microscopically. It is impossible to say in this case that the part of the margin of the ulcer on which the carcinoma developed was also the part where friction of food was greatest.

CASE 2.—This case I have not observed clinically, and no history is at my disposal. As the illustration shows, there is a large, and but slightly elevated tumor mass, which involves almost the whole circumference of the stomach. This is a carcinoma, in the center of which (Fig. 2) we see clearly the quite well-defined edges of a typical round ulcer of the stomach, the whole margin of which is involved and from here the growth has spread quite evenly in all directions. The carcinoma is surrounded by perfectly smooth, glossy mucous membrane which shows the extremely developed effects of a chronic, atrophic gastritis. This case also shows the development of carcinoma from an ulcer, but it has no bearing on the principal question which interests us, and I may say here that we have little cause to expect much in this respect from the small typical round ulcers, as we will but very seldom find the carcinoma so early that it only involves a part of the edge, the rest becoming involved rather rapidly. However, these cases must be recorded and also carefully studied.

CASE 3.—Mr. S., 62 years of age, comes from a healthy family and has always been healthy. His habits have been good, but he has always had a great fondness for sweet pastry. At the age of 30, he suffered from dyspeptic symptoms, lost flesh, became very anemic, and after this he always complained of great sensitiveness of the stomach. About three years before his death he felt badly for some time, as pains in the stomach occurred after meals, which were of a very trying character. Occasional fainting spells set in and the patient lost steadily in weight. About a year before his death, the patient had a hemorrhage from the stomach a few moments after I had stated the presence of free hydrochloric acid in the gastric juice. Then came several hemorrhages from the stomach, and after much pain the patient died on Nov. 14, 1895, at the age of 64.

At the postmortem examination a large irregular ulcer was found in the pyloric region, the longest axis of which was at right angles to the long axis of the stomach. The basis of the ulcer penetrated deeply, in a diagonal direction, into the walls of the stomach, and was here overlapped by a precipice formed by the inner parts of the walls of the stomach along the lower margin. This margin was very much thickened and elevated above the rest of the mucous membrane; it narrowed the pylorus, and was carcinomatous all through. One of the lateral margins of the ulcer (the left one in Fig. 3)

was also carcinomatous and had become ulcerated, while the right one, and the greater part of the upper, had not yet become involved. As Fig. 4 shows, there were a number of metastases in the liver.

If this case does not represent an exception, then it shows very plainly, indeed, that the formation of carcinoma, occurring from an ulcer in the pyloric region, develops from the parts which form the lower margin and which overlap the lower cavity of the ulcer: that means, from those parts which are exposed to the greatest friction by the food.

CASE 4.—Mr. X., 45 years of age, was ailing for about one and a half years, suffering from symptoms of an ulcer of the stomach, such as dyspeptic symptoms, severe pains after meals, anemia, and emaciation; as the pains became more intense, and more constant, the patient commenced to lose in weight more rapidly. He vomited considerably and at last could retain nothing, and died very suddenly, after an attack of intense pain in the region of the stomach.

The postmortem examination of the stomach revealed a chronic gastritis and a long, slit-shaped, deep ulcer (Fig. 5) just in front of the pylorus, with its longest axis at right angles to the longitudinal axis of the stomach. The ulcer deeply undermines the lower margin which overlaps to form a precipice, as in the previous case. This lower margin, as well as the right one, are carcinomatous, while the upper margin is free from carcinoma. The pylorus is filled with carcinomatous masses which have completely obstructed it, and at the basis of the ulcer a small opening is found which is due to a rupture of those parts. This case shows just as clearly as does Case 3 what I intend to prove.

CASE 5.—Mr. X., 72 years old, comes from a healthy family, but one brother died of carcinoma. The patient was always healthy and could eat and drink what he pleased without experiencing discomfort from the stomach. About eighteen months before his death, he drank some cold beer, which caused him to vomit and brought on such pains in the stomach that he could not take any food for a whole day. He recovered from this, but at times would vomit, particularly when he was warm and drank cold beer. He never vomited blood. From this time, although feeling well, he continued to lose in weight and soon meat caused him to vomit. About a year before his death, the patient commenced to suffer a great deal; the pains which up to this time had only come on after the drinking of something cold, now occurred between meals and at night. Five or six months before his death, he commenced to vomit blood, and the vomiting of food became more and more frequent, until one night, after an attack of pain in the stomach, death occurred, under similar circumstances to those in Case 4.

At the postmortem examination a large ulcer was found in the pyloric region, reaching into the pylorus (Fig. 6). The ulcer was not deep, and, therefore, the lower margin did not overlap as much as in Cases 3 and 4. Carcinoma had developed from the lower pyloric edge and from one side-margin, while the upper edge of the ulcer was unaffected. The pylorus had become completely obstructed by carcinomatous masses and rupture of the basis of the ulcer had occurred here, as in Case 4. This case also is well adapted to prove our contention.

Case 6 was observed by Dr. H. J. Haiselden. The patient, a man of 41 years, had had disturbances of the stomach, with a burning sensation for about eleven and a half years. After he had been sick for three months, a physician diagnosed a gastritis. There were periods when the disturbances would cease, but they would return shortly, and a half year ago intense vomiting began, although the patient could sometimes eat raw eggs and other food and retain it. On Feb. 7, 1901, the patient

was admitted to the hospital, vomited a brownish liquid and died soon afterward.

The postmortem examination of the stomach revealed a shallow ulcer which reached from the pyloric region into the pylorus to the duodenum, and from the sides of which a carcinoma had developed in the pylorus, while the upper margin presented no carcinomatous involvement (Fig. 7). Considerable thickening of the mucous membrane from chronic gastritis was present. In this case the lateral margins of the ulcer in the pylorus have been those most exposed to friction. When the pyloric ostium is narrowed by thickenings, its walls being rigid from chronic gastritis, hypertrophy of the muscularis, etc., carcinoma may sometimes develop here without an ulcer being present. I have seen many of these very shallow ulcers in the pylorus and believe that carcinomata develop from them. In such cases all traces of the superficial ulceration are soon lost and the real mode of origin of the carcinoma is then not suspected.

As it is necessary, in order to prove the origin of carcinoma from ulcer of the stomach, not only to consider the pathologic findings, but also the clinical course of the two diseases, I shall bring now, in addition to my own cases here reported, a number of short extracts from such cases, to be found in the literature. This will enable the reader to form his own conception of the clinical varieties of the conditions in question, which is better than if he confines himself to my own, probably too well outlined clinical picture. From the great number of cases of combined ulcer and carcinoma of the stomach, or rather, carcinoma developing from ulcer of the stomach, which I have observed clinically, I have only reported those in which either an operation or a postmortem examination and a thorough microscopic study have revealed the exact nature of the conditions found. It is not to be expected, nor is it advisable, that I should require a microscopic diagnosis in the cases cited in literature, for, while microscopic reports are desirable, their absence would compel me to eliminate nearly all the references. I shall, therefore, bring only such cases from the literature in which the genuineness of the reported findings is guaranteed by the name of the author, and the clinical history is borne out by the pathologic findings, either at operations or postmortem. It is not only my intention thus to report cases, but also to give the opinions of men whose statements are worthy of consideration.

Dittrich<sup>1</sup> described eight cases of ulcer of the stomach, complicated with carcinoma.

CASE 1.—Woman 50 years of age, with hardening of the pyloric portion and a medullary carcinoma in its mucous membrane, on the posterior wall of the stomach; near the lesser curvature were several deep cicatrices from ulcers. (Case not sufficiently well described.)

CASE 2.—Man 50 years of age, fruit-vendor. Medullary carcinoma of the pylorus and a deep stellate scar from an ulcer near the lesser curvature, on the posterior wall of the stomach. (Case not well enough described.)

CASE 3.—Woman 70 years of age, medullary carcinoma in the middle part of the stomach. Several star-shaped scars from ulcers. (Not very well described.)

CASE 4.—Woman of 35 years. Carcinoma of the liver and the peritoneum; a medullary carcinoma of the glands of the abdomen and in the mucous membrane of the stomach, in which deep, stellate scars are found. (Not adequately described.)

CASE 5.—Woman 55 years old. Great shrinking of the stomach, caused by many scars from ulcers. Medullary carcinoma of the cardia. (Not well enough described.)

CASE 6.—Woman 75 years of age. Medullary carcinoma

reaching from the duodenum into the pylorus, on the posterior wall of the stomach; near the lesser curvature, an ulcer with fibrous edges; at its basis, the pancreas. (Not well enough described.)

While it is probable that in these six cases of Dittrich carcinoma has developed from ulcer, this does not fully develop from his description. The next two cases are better.

CASE 7.—Man of 46 years, with round ulcer of the stomach the size of a silver dollar. At the basis of the ulcer, the pancreas, and developing from the edges of the ulcer, a carcinoma.

CASE 8.—Woman of 54 years. Hardening of the pylorus and medullary carcinoma of its mucous membrane. Stenosis of the pylorus. On the posterior wall of the stomach, near the lesser curvature, a round ulcer the size of a silver dollar. At the basis of the ulcer, the pancreas, and at its upper margin, a medullary carcinoma.

After observing these eight cases Dittrich comes to the rather strange conclusion that no particular connection exists between the ulcer and the carcinoma, believing that the simultaneous development of both is purely accidental, and he considers this proven by the location of the carcinoma at the ulcer margins, without involvement of the bases of the ulcer. Carcinoma always develops from the edges and only secondarily involves the basis of those ulcers.

We will add another one of Dittrich's cases:

CASE 9.—Man 50 years of age. Scirrhus and medullary carcinoma of the pyloric region. In front of the carcinomatous part, surrounded by perfectly healthy mucous membrane, a deep cicatrized ulcer. (This case seems to be similar to my cases, Nos. 3, 4 and 5.

Hughes<sup>2</sup> describes a case in which, without a doubt, carcinoma has developed from ulcer of the stomach, and as the clinical history, which dates from the year 1844, is very clear and characteristic, it shall be reported:

"Mary Ann Ramsey, 43 years of age, a widow, was admitted to Allison's wards in the Royal Infirmary, on August 25, 1844. She reports that her menstruation had ceased to come two years ago, and that she has been ailing since. For ten years she has had pains in the stomach after meals, off and on, and after the cessation of the menses these pains have become more intense and more constant in character. In October she was treated in the Infirmary for her stomach trouble, and at the time of her leaving the hospital she was free from pains. Three months after her dismissal, her pains returned, accompanied by sour belching and transitory diarrheas, which symptoms continued. Blood vomiting did not occur."

"Postmortem Findings.—The stomach was much dilated and filled with semi-liquid masses. The pylorus much narrowed by a carcinomatous new formation, so that it was hardly possible to introduce the fourth finger. Reaching from the pylorus, an ulcer was found on the posterior wall of the stomach, two inches in diameter which had led to the formation of adhesions between the wall of the stomach and the pancreas. The margins of the ulcer were elevated almost an inch above the surface of the mucosa; they were of soft consistence, breaking down under the touch of the finger and forming a dirty, whitish mass. The basis of the ulcer was formed by the muscularis, etc."

Hughes has also made a microscopic examination, and he says concerning it: "The tumor mass consisted of a fibrous matrix, the meshes of which were filled with numerous cancer cells and free cells." But, after these observations and this description, Hughes says: "This case is extraordinarily interesting in many ways, and, according to my opinion, it brings a strong proof of the spontaneous healing of carcinoma in an organ." It is to be deplored that Hughes came to such wrong conclu-

sions after his careful clinical and anatomical examinations.

H. Lebert<sup>3</sup> describes the following cases:

CASE 1.—Carcinoma of the heart, the pleura, the peritoneum, the lymphatic glands. The stomach is large and ulcerated, with scirrhus of the pylorus; at the lesser curvature is an old, simple chronic ulcer of the stomach, adherent to the pancreas, and at its basis are small, carcinomatous nodules—there are none at the edges of the ulcer.

If Lebert had made a careful microscopic examination of the edges of the ulcer he would have found carcinoma there.

CASE 2.—Carcinoma of the pylorus, with slight stenosis. Above it is an ulcerous depression, the walls of which are adherent to the liver, which shows no cancerous elements. A simple ulcer.

CASE 3.—On the anterior wall of the pyloric region, a carcinoma of the size of a pigeon's egg, and slight stenosis. In the middle of the lesser curvature, a stellate, pigmented scar, from a simple ulcer.

CASE 4.—Man of 35 years. Has had pain in the stomach for six years. Signs of ulcer, and later, signs of carcinoma. Post-mortem examination reveals perforative peritonitis. The stomach occupies a slanting position and the pyloric portion is considerably lower than normal. In the anterior wall of the stomach, 2 cm. from the pylorus, a large round ulcer of seven cm. diameter, bulging upward, is found. On the anterior wall, near the lesser curvature, the basis of the ulcer is very hard, and covered with warty excrescences, which measure up to 1.5 cm. in thickness. The ulcer is adherent to the head of the pancreas and the examination shows carcinomatous elements. The muscularis is thickened to some distance. In this case, a simple ulcer must have existed for years, and become carcinomatous later.

CASE 5.—Carcinoma of the stomach, in the region of the pylorus. At the larger curvature a simple, not hardened and not infiltrated ulcer, with a perforation into a space closed by adhesions outside of the stomach.

CASE 6.—This man of 46 years has had symptoms of chronic ulcer of the stomach for six years. After a marked improvement, it had recurred six months before his death and gradually all symptoms of a deeper carcinomatous affection developed. At the postmortem examination, carcinomatous nodules were found in the liver and in the pyloric portion a large shallow ulcer, which appeared healed and cicatrized, but at its margin there was thickening and at its basis, firm infiltration, both of which on microscopic section were found to consist of carcinoma cells. In this case, without doubt the long-existing, simple ulcer, has become the site of a carcinomatous infiltration, from which have originated metastases of the liver.

CASE 7.—In this case, which is similar to the preceding one, the stomach adhered to the liver, and at the place of such adhesions there was an ulcer of the stomach at the lesser curvature, which was of the size of a dollar and in which an artery had become eroded; in consequence, two pieces of coagulated blood were found in the stomach. The basis of the ulcer was smooth, somewhat hardened and its edges showed walled hardening, while two secondary carcinomatous nodules were found in the mucous membrane near by. All the anatomical characters indicated secondary carcinomatous affection of the margin of an ulcer.

CASE 8.—The stomach shows a scar from a chronic ulcer at the lesser curvature, and touching the scar, a carcinoma at the lesser curvature.

Brinton<sup>4</sup> reports the following case which he observed in April, 1857:

The patient, a woman of 41 years, married, had, in the course of twenty years, suffered from pains and disturbance of the stomach. At the age of 41, intense pains in the epigastrium appeared and there was vomiting after meals, the latter becoming more and more frequent and troublesome. The patient was admitted to the Royal Free Hospital where she found relief and where she improved, after dieting for some time. After

# THE ORIGIN OF CARCINOMA OF THE STOMACH FROM CHRONIC ROUND ULCER OF THE STOMACH.

G. FÜTTERER, M.D.

Fig. 1.—Adenocarcinoma of the stomach, originating from a very small typical round ulcer. (Fütterer's Case 2.) Natural size. The resected piece was cut in two and we see only one-half of the ulcer and a little more than one-half of the adenocarcinoma, which appears in form of two grayish nodules at the lower edge of the ulcer.

Fig 2.—In the center a well outlined round ulcer and spreading from here in all directions a shallow carcinomatous growth. (Fütterer's Case 2.)

Fig. 3.—Stomach and piece of duodenum opened. In the pyloric region a large and deep chronic ulcer, the lower or pyloric carcinomatous edge stands out firmly infiltrated while the left edge shows carcinomatous ulceration. The upper and right margins are as yet almost free from carcinomatous changes. (Fütterer's Case 3.)

Fig. 4.—Cut surface of liver with six whitish metastatic nodules. (Fütterer's Case 3.)

Fig. 5.—Stomach opened. Chronic gastritis. Deep chronic ulcer in the pyloric region; from the lower and right margins has developed a whitish carcinomatous mass that obstructs the pylorus. (Fütterer's Case 4.)

Fig. 6.—Large ulcer in the pyloric region from the pyloric and lower edge of which has developed a whitish carcinomatous mass that obstructs the pylorus. (Fütterer's Case 5.)

Fig. 7.—Stomach opened. Chronic gastritis. Shallow ulcer in the pylorus, from which has developed a whitish carcinomatous mass that narrows the pylorus. (Fütterer's Case 6.)

Fig. 8.—Stomach opened. Chronic gastritis. Typical chronic round ulcer of the stomach.

Fig. 9.—Microscopical section from the edge of a typical round ulcer of the stomach, showing the upward bending of the muscularis as described by Hauser.

Fig. 10.—Profile of the specimen represented on Fig. 5. Typical "fishhook-form" of the ulcer, with carcinoma, as described by Försterer.

Fig. 11.—Typical chronic gastric ulcer produced in a rabbit, with great thickening of the mucosa, mainly on one edge, but also some on the other. Adhesions between stomach and liver.

a little the pains returned, she became emaciated and died within a few days.

At the postmortem examination, in the middle third of the stomach a large ulcer was found, which had neither affected the cardiac portion nor the pyloric portion of the stomach. It had caused such a contraction of the middle part of the stomach as to change this to a small tube into which the thumb could hardly be introduced. There were adhesions with the liver and the abdominal coverings, but particularly at the place of contraction were found carcinomatous masses, measuring up to one-half inch in thickness. "It was one of those cases in which an ulcer of the stomach had undergone carcinomatous changes. The carcinoma had developed from the edge of the ulcer and had then grown into its basis." In another place Brinton says: "As the ulcer of the stomach has no properties which protect against carcinoma, we must not be surprised to find its scars even in stomachs which later become affected by the more deadly malady. Open ulcers and carcinomata are not seldom found together, and we must suppose that in such cases the carcinoma has been added to the ulcer and not the ulcer to the carcinoma. According to my knowledge, it has not been proven by authentic observations that an ulcerated stomach has become affected with carcinoma without the ulcer itself becoming affected—at least its edges or its basis." *From this it is seen that Brinton had a remarkably clear and correct conception of the conditions in question.*

The histories and postmortem findings so far reported surely speak plainly for the origin of some cancers of the stomach from gastric ulcer, and the following authors, Rokitsky, Liston, Waldeyer, Leube, Zenker and Potain have expressed themselves to the same effect.

Rokitansky<sup>5</sup> (1849): "There are cases in which we can see plainly that a carcinoma has developed from an ulcer of the stomach." This is the first plain, clear and positive statement of its kind that I have found in literature.

Liston<sup>6</sup> says: "The fact that a carcinoma can develop from a simple ulcer of the stomach seems already to have been well proven."

Waldeyer<sup>7</sup> (1872): "I do not hesitate to say that a simple ulcer may, in the course of time, be changed to a carcinoma, if the epithelial elements, instead of undergoing degeneration, take part in the process of proliferation on the edges of the ulcer."

Leube<sup>8</sup> (1874) rightly considers the observations of carcinoma with chronic round ulcer of the stomach not only interesting from the anatomic and pathologic standpoints, but also in reference to its etiology.

Zenker<sup>9</sup> (1882), who demonstrated a specimen in the Nürnberger Aerzteverein, expressed the opinion that a carcinoma had developed secondarily from an old chronic ulcer of the stomach. This specimen was then described thoroughly by Hauser in his well-known monograph.

Potain<sup>10</sup> (1883) also says that the carcinoma of the stomach has a great tendency to develop from old scars.

All the clinical and pathological observations and the opinions which we have so far cited are of great importance. But the question whether it is really true that carcinoma comes secondarily to an ulcer of the stomach, or whether the ulcer or the scar are a product of the carcinoma, can not be finally decided from these considerations. Hauser<sup>11</sup> in his excellent monograph which appeared in 1883, under the title, "The Chronic Gastric Ulcer, Its Mode of Cicatrization and Its Relations to the Development of Carcinoma of the Stomach," has thrown more light upon this subject. Hauser studied and described the above-mentioned case of Zenker and also a carcinoma of the stomach which had been resected by Heinecke, and he observed peculiar conditions of the

muscularis which he rightly considered to be characteristic of an ulcer of the stomach. He says: "Closely above the edge of the ulcer, we see muscularis going upward in a diagonal direction towards the mucous membrane, and to become connected with the muscularis mucosa which here is interwoven with a great deal of connective tissue. In this way the muscularis becomes thoroughly separated from the basis of the ulcer, which here consists only of a thick layer of connective tissue, and the line of separation is here, as the muscularis is turned upward, formed by the lower parts of the muscularis." Again he says: "In a primary carcinoma of the stomach which has become ulcerated, we will never find such a sharp division between the muscularis and the other tissues at the basis of the ulcer; and this line will never be formed by the lower zone of a muscularis that has been turned upward."

It is not hard to convince ourselves of the correctness of Hauser's views, and I give here two illustrations of which the first shows the muscularis in a simple gastric ulcer (Fig. 9), and the second in gastric ulcer with carcinomatous changes (Fig. 10). The second illustration shows the profile of the ulcer, on which we can observe the upward bend of the muscularis toward the mucosa, very satisfactorily. *But it shows something also, which I consider of no less importance. That is a typical fish-hook shape.* From my observations, I have concluded that we may safely take it for granted that an ulcer found together with carcinoma of the stomach, has been a typical ulcer, when this fish-hook form is found. I think we must differentiate between very shallow, irregularly formed ulcers, typical round ulcers, and rather multiform ulcers of the stomach, which often are very deep, for it is surely not right to call a thing round which is not round, and we do that if we call all ulcers of the stomach round ulcers. We can not say that the larger ulcers have a very characteristic form, for, although they are called "ear-shaped" it often requires a very great deal of imagination to discover the similarity between the form of such an ulcer and an ear. While the forms as seen from the surface are so variable and have nothing characteristic, I wish to state that the profile shows forms which are far more constant. The formation of the fish-hook-shaped profile underlie the same laws as those which determine the progress of the ulcer into the deeper layers of the stomach walls and this guarantees the constancy of its occurrence. In the smaller or more superficial ulcers no typical fish-hook form can be expected, and it is then that the condition of the muscularis, as described by Hauser, gives valuable information.

After Hauser's observations bearing on the relation of the muscularis to the basis of the ulcer, and after my own observations concerning a characteristic profile—the fish-hook shape—it may be taken as proven that carcinomata do develop secondarily from ulcers of the stomach. Since the publication of Hauser's monograph in 1883, the following cases have been reported:

Hanot<sup>12</sup> observed a case in a woman 42 years of age: a carcinoma had developed from the edges of an ulcer, which was located in the pyloric region.

Thiersch<sup>13</sup> saw a carcinoma at the basis of an ulcer.

Rosenheim<sup>14</sup> reported three cases:

CASE 1.—Woman, 42 years of age, suffered for ten years from attacks of gastritis. For nine months she had constant nausea, a feeling of pressure in the epigastrium and sensitiveness to pressure; black vomit. Postmortem findings: Carcinoma in the pyloric region, which had developed from an ulcer.

CASE 2.—Woman, 58 years of age. Insufficiency of the mitral valve for twenty years. Six months ago, pains in the epigastrium developed, which became more violent as time advanced, and which weakened the patient very much. Later, there was black vomit. The pains and vomiting continued up to the death of the patient, a year after the appearance of the first symptoms. As emaciation had progressed during the last months of her life, a tumor could be felt under the left costal arch. The postmortem examination revealed a scirrhus which had developed from an ulcer.

CASE 3.—Woman, 64 years of age, had suffered from stomach trouble for three months. The stools were tar-colored and the patient often vomited bile. Postmortem findings: Near the pylorus an ulcer with eaten edges, which were carcinomatous. Only a small part of the margin was not involved by carcinoma, and this was the pyloric margin.

Krukenberg<sup>15</sup> describes a case in which a glandular carcinoma had developed from the margin of a cicatrizing ulcer.

Goodhart<sup>16</sup> reports the postmortem findings in a man 32 years of age, consisting of a glandular carcinoma near the pylorus with a long excavation that makes it appear probable that the primary affection had been an ulcer of the stomach.

Häberlin<sup>17</sup> reports fourteen cases in which carcinomata have developed from ulcers of the stomach, but I have only selected four of them:

CASE 1.—Man of 30 years, had suffered from stomach trouble for three years. He vomited almost daily, but never blood, and the postmortem examination showed a deep ulcer of the pylorus surrounded by nodular growth.

CASE 2.—Woman of 39 years, admitted on Oct. 21, 1886. Six years before, at the age of 33, she was very anemic, and during the last six months before her death emaciation developed. There were pains in the stomach, vomiting, but no blood. Died on Dec. 19, 1896. Postmortem examination revealed carcinoma which had developed from gastric ulcer.

CASE 3.—Man of 66 years, admitted on Sept. 29, 1885, had suffered from pains in the stomach since about his 26th year. Frequent vomiting and emaciation. Died on Oct. 16, 1885. Postmortem examination showed carcinoma and ulcers at the pylorus.

CASE 4.—Woman of 51 years, admitted on Oct. 5, 1886. Complained of gastric pains and vomiting; no hemorrhage; emaciated. She died on Dec. 15, 1886. Postmortem findings: Carcinoma and ulcer.

Koch<sup>18</sup> reports the case of a woman of 36 years in whom an ulcer was diagnosed, but a suspicion of carcinoma was entertained, because of rapid emaciation, unsuccessful ulcer treatment and the presence of large quantities of lactic acid. Postmortem examination showed the development of a carcinoma from a scar in the pyloric region.

Gravenhorst<sup>19</sup> saw a case of carcinoma that had developed from ulcer of the stomach, without causing any clinical symptoms.

Maillefert<sup>20</sup> In his third case cicatrizing ulcers had produced an hour-glass shape of the stomach which was surrounded by carcinomatous masses.

Hemmeter and Ames<sup>21</sup> Man of 56 years who had been under observation for two years and at first showed plain symptoms of ulcer of the stomach. Postmortem examination: Near the pylorus an ulcer, and a carcinoma had developed from the pyloric margin of the ulcer.

Hickman<sup>22</sup> Woman, 29 years of age, had had gastric pains before she was admitted to the hospital. Postmortem examination: Dilatation of the stomach. In the pyloric region, at the lesser curvature, was a scar one and one-half inches in diameter, and nearer the pylorus a carcinoma.

To facilitate references, we shall now bring the cases already mentioned, and others, in the form of a table.

LIST OF CASES FOUND IN THE LITERATURE, IN WHICH CARCINOMA HAS DEVELOPED FROM CHRONIC ULCERS OF THE STOMACH.

| No. | Reported by       | Sex. | Age. | Localization of the ulcer.   | Localization of the carcinoma.                                 |
|-----|-------------------|------|------|--|--|
| 1   | Dittrich          | F.   | 50   | Posterior wall near lesser curvature.                                    | Pyloric portion.   |
| 2   | "                 | M.   | 50   | Deep stellate scar on posterior wall near lesser curvature.              | " "  |
| 3   | "                 | F.   | 70   | Middle of posterior wall.  | Middle of posterior wall                                       |

| 50  | "                 | M.   | 45   | "  | Pyloric edge of the ulcer.                                     |
| 51  | "                 | M.   | 72   | "  | As above.  |
| 52  | "                 | M.   | 41   | "  | As above.  |

Many of these cases have been incompletely described, sometimes sex and age have been omitted or the localization of ulcers and carcinoma and their exact relations to each other have been but vaguely referred to. I am convinced that a more accurate description would give us a deeper insight into the relations existing between carcinoma and ulcer of the stomach, and I also believe that good illustrations would be valuable and would often make up for deficiencies in description. A thor-

ough observation and description of cases would soon show that our standpoint in the matter is well taken. Of course, the number of cases thus found will be but small as compared with cases that are clinically observed, where no operation is performed and no post-mortem or no microscopical examination has been made to put the stamp of correctness on the clinician's opinion. Our table contains fifty-two cases—females nineteen, males twenty-four, sex not given, nine. The age ranges from 26 to 75 years—in the females from 29 to 75, in the males from 26 to 72. In 10 cases the age was not given. The localization of the ulcer is not given in forty-five cases; pyloric region in thirty-seven cases; lesser curvature in nine cases; larger curvature in one case, the middle of an hour-glass shaped stomach in 2 cases. The following authors mention the development from the edges of the ulcer: Dittrich, Cases 7, 8, and 9. Hughes and Brinton note the development of carcinoma from the scar of an hour-glass shaped stomach. Lebert, Cases 4, 6, 7, and 8; Hauser, Hanot, Rosenheim, Case 3; Krukenberg, Goodhart, Tapret, Eisenlohr, Koch, Pitt, Maillefert, Packard, Biach, Hayen, Dieulafoy, Hemmeter and Ames, Hickman, Fütterer and Billings. The localization of carcinoma at the lower pyloric edge of ulcers was noted by Dittrich, Case 9; Hughes, Goodhart, Eisenlohr, Pitt, Hemmeter and Ames, Hickman and Fütterer, Cases 3, 4, and 5; but not one of these authors, with the exception of the last, has considered the importance of this fact, or has tried to explain it, while we consider it of the highest importance in explaining the etiology of carcinoma in general.

#### CONCLUSIONS.

After what has been said, we would emphasize the following points:

1. If a carcinoma develops from a chronic ulcer of the stomach, then this development occurs from those parts of the edges of the ulcer which are most exposed to mechanical irritation by the contents of the stomach.

2. In the pyloric region, it is the lower pyloric margin of the ulcer which is most exposed to mechanical irritation and from which carcinoma develops. But other parts of the edges may be the ones involved when dilatations and adhesions have changed the position of the organ.

3. Development of carcinoma from ulcers of the stomach in the pyloric region occurs with great frequency, while such a development occurs less often in other parts of the stomach.

4. If what has been said under our third conclusion is correct, then we must in all cases in which an ulcer of the stomach or its scar narrows the pylorus, recommend early a gastro-enterostomy, to prevent the development of carcinoma. If a gastro-enterostomy has been made, then the mechanical irritation of the ulcer in the pyloric region by food is reduced, and the severe friction necessary to produce a carcinoma will probably not occur.

5. A patient suffering from the consequences of a stenosis of the pylorus, particularly if this is caused by ulcers and scars, should, if a gastro-enterostomy is not performed, be advised to eat slowly and little at a time, and to be particularly careful about carbohydrates and especially hard crusts of bread; they should avoid crisply fried, or other coarse food, and they should, as much as possible, confine themselves to liquid or semi-liquid foods. A good deal of fatty food should be recommended.

6. Elderly people in particular, who have but few or

no teeth and a saliva which is insufficient in quantity and quality must be most carefully advised as to their diet, and to such cases taka-diastase should be administered.

7. From the fact that carcinoma does not develop from the large ulcers alone, but may be developed from the very smallest, the prognosis of ulcer of the stomach is bad. Our aim, therefore, should be to prevent the formation of ulcers, rather than to heal them after they are formed, and this may be done, at least to a certain extent, by the energetic treatment of all cases of chlorosis and secondary anemia that come under our observation.

8. After reviewing the literature, we are now in a position to say that no one before us has laid stress on the fact that carcinoma of the stomach, which develops from an ulcer, originates from certain parts of their edges, and that this, while of importance in itself, will prove to be of great value when it is sufficiently considered in reference to the etiology of carcinoma in general.

My experimental work on the stomachs of animals has furnished sufficient corroborating facts, inasmuch as proliferation of the elements of the mucous membrane of the stomach occurred on edges of ulcers which had been produced by experiment. The histological qualities of such proliferations were those of an adenocarcinoma, as described in our Case 1, and, while I do not wish to state that I have produced a malignant growth with all its inherent peculiarities and sequelæ, such as, for instance, metastasis and cachexia, I do wish to give it as my opinion that histologically there was adenocarcinoma, and that I fully believe that further work in this direction will lead to the production of a true carcinoma by our method. The last cut represents such an ulcer in the stomach of a rabbit, and it is easy to notice the difference in the condition of the mucous membrane at the upper and the lower edge of the ulcer. For a more detailed description of the finer histological changes, I must refer the reader to my monograph, which has already been mentioned.

# PNEUMATIC DIFFERENTIATION IN THE TREATMENT OF ORGANIC DISEASE OF THE HEART.\*

CHARLES E. QUIMBY, A.M., M.D.  
NEW YORK CITY.

It is the purpose of this paper to present a physical demonstration of the value of pneumatic differentiation in the treatment of organic cardiac disease, and to adduce clinical evidence in proof of the accuracy of such demonstration. The propositions on which this treatment is based were definitely formulated before any clinical application was made. Such application was begun with absolute confidence as to the character of the results, but, it must be confessed, without the least suspicion of their extent. The clinical evidence presented is derived from nine years' use of the cabinet in the treatment of, essentially, all forms of organic cardio-vascular disease. The proposed physical demonstration requires:

I. Consideration of the physics of the circulation and its relation to tissue nutrition as the basis of functional activity.

II. Determination of the dynamic and nutritive disturbances involved in pathic conditions, and the possibilities of their modification.

III. Presentation of the physics of pneumatic differentiation and its action, as applied to the circulation, in modifying pathic conditions.

## VASCULAR PHYSICS.

I. It is a physiological axiom that the function of the heart and vessels is, primarily, purely mechanical, and consists in the propulsion of blood in a given direction and appropriate quantity. This object is attained by the development of a permanent arterial tension, and alternating differential tensions in adjacent vascular cavities, the lower tension being always on the side of the direction of the blood current. Vascular tension is thus seen to be, from the standpoint of pure physics, the sole factor determining the circulation *per se*, and the point at which all disturbances of that circulation will be first manifest.

Were the sole effect of vascular tension that of blood propulsion, and the conditions under which this propulsion takes place constant, we might affirm that the absolute degree of tension was of no importance so long as the established differential tension ratios were maintained. But when we consider the mechanism concerned in the production and maintenance of these varying blood tensions, and their relation to nutritive interchange, it immediately becomes apparent that disturbances in tension ratios are pathic largely by very reason of their effect upon absolute tension. There is no longer any question as to the effect of persistent increased blood tension upon the vascular mechanism. Nor can it be denied that even minor grades of fixed increase are essentially pathic; for, although they may be attended by complete compensatory hypertrophy of the circulatory organs for a prolonged period, sooner or later the powers of nutritive repair fall below even this slight increased demand and circulatory failure results. But when the increased tension is itself the result, and compensatory hypertrophy react, each to increase the other, thus hastening the progress toward the point where compensation fails; so that such increased tension becomes self-

destructive through those very changes which it calls forth for its own maintenance.

Hence, so far as relates to the circulatory mechanism, we have this as our first proposition:

1. The maintenance of the circulation and the preservation of the vascular mechanism demands not only the continuance of differential blood tensions and their rhythmical alternation, but also the restriction of the absolute degree of such tensions below an established limit.

Turning to the relation of absolute tension to nutritive interchange, since pneumatic differentiation, as will be shown later, lowers absolute tension while increasing tension ratios and thus develops increased quantitative flow, we have to consider only the effect of such modification of circulation. While twenty years ago much stress was laid upon the dependence of nutrition on vascular tension, recent investigations have seemed to show that the highest nutritive activity is determined by the quantitative blood supply rather than the tension.

2. However, as a clinical answer will be given later so far as bears upon the subject in hand, suffice to say here as a justified conditional proposition, that if full

Fig. 1

Fig. 2

nutrition can be maintained through increased blood flow under lowered tension, such a condition must afford relief to the vascular mechanism and, hence, tend to prolong its period of functional activity.

From these two propositions we deduce our first therapeutic premise: that any agent which maintains tissue nutrition and functional power, and lowers vascular tension, thereby relieving cardio-vascular strain, is, in character, an ideal therapeutic measure in organic cardiac disease.

## DYNAMIC AND NUTRITIVE DISTURBANCES OF CARDIAC DISEASE.

II. The primary and only directly dependent result of essentially every cardiac lesion is a change in the absolute degree of blood tension and in tension ratios. This change consists of a decrease of tension in the systemic vessels and increased tension in some cardiac cavity. The result of the former is lessened blood flow, diminished tissue nutrition, and consequent arterial contraction to restore blood pressure and current. In response to the latter, which is now augmented by the reflex rise in arterial tension, there is developed a compensatory hypertrophy of the propulsive mechanism, which involves thereafter a persistent excess of force expenditure. So long as this hypertrophy and expenditure keep pace with the demands of increasing tension there is, physi-

\* Read before the New York State Medical Association, October 23, 1901.

cally speaking, full compensation. But hypertrophy and tension react to increase each other and thus hasten the passage into degeneration with lessening propulsive force, decreasing arterial tension, and failing systemic nutrition, i. e., death.

It is thus seen that every cardiac lesion excites, solely through vascular tension, reactionary changes, which are compensatory and conservative only within certain limits, beyond which they become destructive, and that the seriousness of any given lesion will be measured, 1. by the absolute amount of increased tension produced; 2. by the capacity for hypertrophy in the tissues called upon to supply compensation, and 3. by the character of the lesion itself, whether fixed or progressive. Each of

nutrition throughout the entire system are ideal therapeutic measures in organic cardiac disease.

Recurring from this to the physics of the circulation, and noting the fact that the blood current, upon which depends nutrition, is maintained only by rhythmical alternations in the tension ratios between adjacent vascular cavities, it is evident that any agent which fulfills the requirements of an ideal therapeutic measure, must not only lower vascular tension, but also develop those alternations of tension required to maintain the circulation.

#### PNEUMATIC DIFFERENTIATION.

III. Upon this basis we turn to the physics of pneumatic differentiation and its application to organic cardiac disease. To appreciate clearly the action of pneumatic differentiation, as applied to the circulation, it is imperative that one keep constantly in mind that fixed term of blood tension which counterbalances atmospheric pressure; for it is upon its power to render dynamic this force that the whole treatment rests. When, for instance, we speak of aortic pressure as so many millimeters of mercury, the absolute tension of the blood is that amount plus barometric pressure at the moment. It is in this commonly ignored term, called reserve tension, that we find the positive force which the pneumatic treatment develops.

Fig 3.—A. Bellows. B. Glass front. C. Stopcock for breathing tube. D. Stopcock for restoring atmospheric pressure in cabinet after treatment. E. Mercurial gauge.

these factors has its special bearing on the possibilities of relief, but the indications for an ideal treatment are precisely the same from all. For, since in every case it is the increased tension which excites all the secondary changes, and its tendencies for evil are compensated only by organic hypertrophy, the duration of any given case will be determined by the ratio between the increased tension and nutritive metabolism in the compensating tissues. Hence, the indications in cardiac disease are to decrease vascular tension and increase cardiac nutrition. From this we have our previous therapeutic premise made more specific, thus: Only such agents as decrease vascular tension and coincidently maintain or increase

Fig. 4.—Interior view of cabinet, showing ozone generator through glass front.

Failure to recognize the potency of this force and its relations to the circulation led to illogical use and condemnation of the cabinet years ago, and still prevents acceptance of the imperative deductions as to its therapeutic value in both pulmonary and cardiac disease.

The apparatus employed in the application of pneumatic differentiation consists of a cabinet, which can be closed practically air-tight, of sufficient size to contain one person. On the top is a bellows by which the contained air can be rarefied or compressed at will. In one side is a stop-cock, through which and an attached tube, the patient's lungs may be instantly connected with or shut off from the outside air, thus instantly changing the pressure upon the pulmonary surfaces and within the thorax from barometric to that of the air within the cabinet. The use of this apparatus in the application of pneumatic differentiation, by which term is meant a differential atmospheric pressure on the cutaneous and pulmonary surfaces, and the physics of its action in modifying the circulation will best be shown by following a patient through the process of treatment.

Reference may be made to Figs. 1 and 2, in which concentric circles represent the systemic and pulmonic

circulations and the shaded interspace the thoracic wall. In Fig. 1 the lung is connected with the outside air and under barometric pressure (LB). In Fig. 2, with the cock closed and the connection broken, both the lung and cutaneous surface are under diminished pressure (LR).

Given a patient in the cabinet, a rarefaction of the contained air is produced of, we will say for convenience, two inches of mercury. The pressure upon the entire cutaneous and pulmonary surfaces is thereby reduced one pound to the square inch and an equivalent amount of reserve tension made dynamic (Fig. 2). As a result the general blood pressure is instantly lowered, giving relief to the left ventricle, and the blood is drawn into the dilated surface and underlying vessels, the action being precisely that of sudden elevation of altitude. Under its continuance there is developed a capillary and arteriole hyperemia, which, by reason of their weaker walls and lack of anatomic support, is most marked in the pulmonary vessels. Thus, through anatomic conditions, atmospheric rarefaction produces

## PI. BCF

relative pneumatic differentiation between the cutaneous and pulmonary surfaces in favor of the latter, whereby the blood is drawn from the systemic into the pulmonary vessels under lowered tension. With the circulation thus at the point of mild pulmonary hyperemia, the patient takes the breathing tube in his mouth, when, as the cock is opened, barometric pressure is instantly restored to the pulmonary and thoracic circulation, which, be it noted, includes the cardiac cavities, and the pneumatic differentiation, now made absolute, is as quickly shifted in favor of the systemic circulation (Fig. 1). The tension ratio between the two circulations is increased, yet with the high tension factor in the thorax only that of barometric pressure. The entire systemic circulation is virtually under the influence of a huge cup. The result is obvious: the blood is drawn from the lungs through the left heart and arteries into the dilated capillaries, the point at which nutritive interchange takes place, almost without aid from the ventricle, and thence flows freely into the veins, which, as the differentiation is maintained, become distended by an excess of low-tension blood. These changes occur while the pa-

tient takes a slow, deep inspiration with, possibly, two or three seconds holding the breath at the end. During this time the left ventricle is, practically, relieved of all work, and, with the pulmonary circulation under only barometric pressure, there is no impediment to the passage of blood from the right to the left heart or strain of the right ventricle. Thus, under lowered tension, the previous localized hyperemia is transferred, through a hastened circulation, from the lungs to the systemic veins. But, before this venous hyperemia reaches the point of slowing the circulation, the valve is closed, the tube dropped from the patient's mouth and instantly the differential pressure is shifted in favor of the lungs again (Fig. 2). Now, with the previous differential ratio augmented by the developed tension of the venous hyperemia, the right ventricle obtains corresponding relief from work as the veins empty themselves through the right heart into the depleted pulmonary vessels until that circulation is again at the point of mild hyperemia, the condition from which we started, and the patient is ready for a repetition of the process. It is thus made evident that pneumatic differentiation, in

## PI. DEG

its application, develops rhythmical alternations of the tension ratio between the pulmonic and systemic circulations, and thereby produces a quickened and augmented blood flow under lowered vascular tension.

What, then, are the relations of this process to the pathic results of the several cardiac lesions?

1. Aortic Obstruction: In this case, while the pathic increase of tension in the ventricle is due to an unalterable condition, the total of ventricular strain is the sum of valvular obstruction and arterial tension. This latter term, which tends to increase with the obstruction, can be diminished by pneumatic differentiation with coincident increase of circulation. The treatment is, therefore, applicable to this lesion. Its power to afford relief will vary with the ratio between tension and obstruction and must be measured by clinical results. Statements bearing upon that point, here as elsewhere, are, therefore, given upon personal authority and not as part of the scientific demonstration. Upon this basis we say that, in all, save the most severe, cases of non-progressive aortic obstruction, and in the progressive cases of old age, arterial tension is the dominant term and can usu-

ally be reduced to such a degree as more than to counterbalance the obstruction, and hence to cause absolute reduction of ventricular strain below the normal, and thus give definite rest to the heart during the period of treatment. Even when there is ventricular failure and low arterial tension the compression of the thoracic organs acts to support the ventricular walls and affords very appreciable relief.

2. Aortic Insufficiency (Regurgitation): It is in this lesion where the destructive results are invariably progressive, even when the valvular insufficiency is constant, that pneumatic differentiation finds its most perfect application. For the first pathic increase of tension in the ventricle, and the consequent eccentric ventricular hypertrophy, which reacts to increase still further arterial tension, depend directly upon arterial tension, the force over which pneumatic differentiation has the most perfect control. Later, when, from failing circulation, a lowered nutrition excites arterial contraction and a still further destructive rise of tension, similarly pneumatic differentiation, by increasing blood flow and nutritive supply, does away with the necessity for high tension and thus makes the low tension which it produces for the relief of cardiac strain compatible with full systemic nutrition. The physics of its application should be evident. During inspiration (Fig. 1), corresponding to six or eight heartbeats, the pulmonary circulation and heart walls are supported by barometric pressure; the systemic circulation is cupped one pound

to the inch, arterial tension lowered, the regurgitant force and current thus diminished, the ventricle allowed to empty itself completely and recover its tonicity, while the blood is hurried through the capillary circulation into the veins. During expiration (Fig. 2) this surplus of blood is drawn into the lungs ready for another circle.

The clinical results are, first, immediate relief of all sensations of distress and the substitution of a sense of rest and refreshment—I have seen a patient's condition change from that of distinct angina to complete relief within five minutes—and second, rapid amelioration and often permanent disappearance of all subjective symptoms with corresponding decrease in the objective signs.

3. Mitral Insufficiency: The amount of reflux and consequent pathic tension is directly dependent on arterial tension. The application of the treatment is, therefore, the same as in aortic lesions. But, as compensation is here from the right heart through the pulmonary vessels, the possibilities of permanent relief are not as great as in aortic insufficiency. Clinical experience confirms this, for while the immediate relief is often

quite as pronounced as in aortic lesions, it is seldom as prolonged.

4. Mitral Obstruction: It must suffice now to say that the form of treatment described above is not applicable to this lesion. Time also compels us to reserve discussion of its relations to the varied forms of cardiac dilatation and muscular weakness for a later paper.

In comparing this method of treatment with accepted therapeutic measures we find but two sets of agents which require consideration: 1, the drugs represented by nitroglycerin, and 2, those measures which dilate the capillaries through reflex demand for widespread tissue repair. While the first class act more powerfully to reduce arterial tension, and thereby afford very great relief from cardiac strain, they do not tend to hasten circulation, save in so far as the heart gains propulsive power through decreased opposition. Indeed, the increased frequency of the pulse under their influence shows that their effect is rather to slow the circulation, and this often makes impossible their persistent use. These drugs, therefore, fulfill but one of the requirements of an ideal treatment, and in so doing oppose the other.

The second class is covered, essentially, by the Oertel and Nauheim treatments, in each of which diffuse capillary dilatation is secured through reflex demand for increased nutrition and tissue repair. Of the two the Nauheim is obviously the better, being essentially the

## Pl. A

Oertel treatment plus the baths. Yet even the Nauheim treatment does not claim to lower arterial tension, but, while offering relief to the heart through reduction of capillary obstruction, at the same time calls for a responsive increased force expenditure. Indeed, Schott states that "it is considered a serious symptom when, in any case undergoing balneologic and exercise treatment, the blood pressure is lowered, and that when the tonometric figure is as low as 65 or 60 mm. of mercury, therapy is of little avail and the bath and exercise both contraindicated." Still further, as showing the direct power of this treatment to influence the circulation, Heinemann, an ardent advocate, says, "that the patient who is being given the Nauheim treatment, and who leaves the bath in the forenoon to encounter later in the day the varied forms of life's mental annoyances, can never hope to receive much or permanent benefit. Freedom from mental irritation during the period of treatment and for a period after treatment is a *sine qua non* to its success."

In comparison with the foregoing, what does pneumatic differentiation accomplish? In cases with high

tension, representing the stage of attempted compensation, it reduces arterial tension, the basic factor of evil in all cardiac disease; it relieves cardiac strain and affords opportunity for tissue repair and recovery of muscular tone; and it simultaneously increases general systemic nutrition through augmented blood flow. When, on the other hand, low tension indicates failing compensation, it again through similarly increased nutrition restores functional power to the vascular mechanism whereby compensation is renewed and arterial tension brought back to the point of maintaining the circulation.

From the above presentation of applied pneumatic differentiation and previously deduced therapeutic propositions, we state, as our final conclusion which was to be demonstrated, that, from the standpoint of applied physics, pneumatic differentiation represents the nearest approach to an ideal treatment for organic cardiac disease of all measures at present available.

To what extent does clinical evidence support the accuracy of this conclusion? In reply we offer, first, sphygmographic tracings, and second, clinical histories, requesting that, for brevity, we be allowed to present them together without regard to logical sequence.

Plate BCF is presented in proof that sphygmographic tracings are of absolutely no value as an index of any spe-

## Pl. C

cific cardiac lesion, but may be made accurate records of relative variations in arterial tension for the time during which they are made, which, by comparison, may prove permanent changes in vascular tension. Of these tracings the last, which is as typical as any one of aortic regurgitation, is the only one which was not from such a case. In the first, third and fifth there is not the least hint of such a lesion.

Plate DEG, all tracings from cases of mitral regurgitation, is further proof to the same effect.

Plate O shows the immediate effect of pneumatic differentiation on arterial tension pure and simple. The tracings are from a hopeless case of chronic Bright's disease, with arterial fibrosis and cardiac hypertrophy passing into failure. The second tracing, taken just after five minutes' treatment at only one inch rarefaction, shows practical obliteration of constant arterial tension and is in marked contrast with the first, taken just before treatment. The third and fourth afford a similar comparison for the second day's treatment, while the fifth, taken before treatment ten days later, compared with the first, shows that a certain degree of

relief is given even in the hopeless conditions. This case is cited just because it presents the worst possible conditions for affecting arterial tension, and the results are, therefore, all the more conclusive.

CASE A.—Male, 38, coachman; was first seen at college clinic early in October, 1895. He has all the symptoms and physical signs of extensive aortic disease; double aortic murmur is heard anywhere on the chest and in the arteries; he has excessive eccentric hypertrophy and commencing dilatation; arterial and capillary pulsation in the extreme; he suffers severely and almost constantly from angina, which was developed acutely by the excitement of appearing before the class; he has not been able to work even in driving for over a year; he sleeps only in erect position and thus but little and interruptedly on account of angina, from which he obtains only partial and temporary relief by large doses (1/25 to 1/12 minim) of nitroglycerin repeated every hour or oftener.

Patient was given ten minutes' cabinet treatment twice a day for a week and then twenty minutes daily. He was suffering from angina on first entering the cabinet; this was greatly relieved the first day; after three days' treatment he slept prone nearly the whole night, and at the end of a week gave up nitroglycerin, except one or two doses the last part of the night. At the end of the second week he disappeared, to turn up again in March, 1896, with this report. At the end of his two weeks' treatment in 1895 he had secured work in the

## Pl. C'

preparations for the horse show, where he had worked that week and the week of the show from early morning until late at night. He then went to Kentucky in charge of a carload of horses, and there got work on a stock farm. In about a month his angina returned, and he took to drink for relief; was soon obliged to quit work, and later returned to New York. His pulse when treatment was resumed (March 9, 1896), is shown in the first tracing, Plate A.

At this time his heart was so weak, his angina so nearly constant and so quickly excited by the slightest change in circulation, that even the treatment tended to develop it. During the first day, therefore, he was kept at the office all day and given four treatments of from five to ten minutes each. The effect is shown in the second tracing taken in the evening. The improvement is obvious, but his statements as to the subjective relief were even more decided. On the 10th and 11th he received three treatments of ten minutes each. The result of these three days' treatment is shown in the third tracing, which is near normal. His angina had entirely disappeared and he felt well. The fourth tracing, taken on the 16th, shows a retrograde change, due to whisky,

and thereafter he came for treatment only at irregular intervals, drinking heavily in the meantime.

**CASE C.**—Male, 40, laborer. As this case was taken solely for purposes of demonstration we beg to condense the history to a simple statement of diagnosis, which was aortic regurgitation, moderate arterial fibrosis, cardiac hypertrophy, and chronic Bright's disease. The patient was fairly comfortable so long as he remained quiet in the hospital, but suffered from dyspnea and thoracic oppression upon any marked exertion.

Turning to the tracings (Plate C) for the results of treatment, it seems difficult to imagine more conclusive proof of the power of pneumatic differentiation to reduce arterial tension and so augment tissue nutrition as to do away with the necessity for its recurrence. The first tracing was taken before any treatment whatsoever, and is typical of an extreme degree of high tension backed by a not over-strong heart. The second, taken directly after fifteen minutes' treatment, shows the same immediate effect upon arterial tension as was seen in Plate O, while the third, taken ten minutes later, shows, in comparison with the first, the extent of arterial and ventricular relief derived from a single treatment. The

## Pl. B"

fourth, taken the next day before treatment, indicates, by comparison with the first, the persistence of that relief. It is seen that while the tension has returned in part, it has not reached its previous degree. The last, taken after treatment this day, shows how at times the treatment apparently has but little immediate effect upon tension while affording marked relief to subjective symptoms.

That the effect was there in this case, at least, appears from Plate C', of which the first pair were taken before and after treatment on the fourth, the second pair on the fifth, and the last on the twenty-fifth day from the beginning of treatment. For the first week treatment was given daily, afterwards three times a week.

This plate shows the practical permanency of the effect on tension, and, with the statement that soon afterwards the patient insisted on leaving the hospital and going to work, affords unanswerable proof of the power of pneumatic differentiation to control the circulation.

**CASE B.**—Male, 36; lawyer; single. Seven years ago, in 1885, he suffered from a most severe attack of endocarditis

and aortitis. Such recovery as he made was gained only after nine months' absolute rest, most of the time in bed, and left him with an extensive aortic insufficiency but poorly compensated. On returning to town he attempted to continue his profession by limiting himself to office work, but the interruptions, at times of several months' duration, incident to recurring attacks of acute dilatation, soon forced him to relinquish even that. He retired to the country where, largely by accident, he became interested in what has proven an immense enterprise. This he was able to carry in its earlier stages because the work could be made to await his ability to do it. As the demands on his strength increased and became more imperative, however, the attacks of heart failure returned with increasing frequency and severity until, just as he was preparing to give up, he was prostrated by an unusually severe attack, and I was first called to attend him. This was seven years after his first attack, during which time he had been constantly under medical supervision. He presented all the symptoms and signs of extreme acute dilatation following aortic insufficiency. The pulse was intermittent, irregular and uneven to an extreme degree. The heart gave loud double aortic and systolic mitral murmurs. He could not lie down and even in the erect position angina was severe and persistent, while the throbbing in his head was even worse. He had learned by sad experience that digitalis only increased the former as did nitroglycerin the latter. My mental prognosis was death at any moment. At the end of about two weeks, however, under aconite, morphia and quinin, he was able to walk about his room without exciting serious increase

## Pl. B<sup>IV</sup>

of cardiac irregularity. A few days later, Dec. 23, 1892, he received his first treatment by pneumatic differentiation. This was given daily for the first two months or so and then daily when he happened to be in town, which varied from two days to two weeks at a time, with intervals of from a day to a month at a time, during which he had no treatment. To summarize results and the history of the past nine years: Before the end of January, 1893, i. e., within less than six weeks, he resumed his business, which he has continued until the present moment, despite constantly increasing burdens, with but a single relapse. For three years he took practically no vacation, but in the spring of 1896, after a winter of unusual business strain, he asked permission to take a rest by a trip abroad, to which hesitating consent was given. Although the voyage was smooth he suffered, contrary to his habit, from seasickness. By the time he reached London he felt the warning headache and called a physician, who at once put him to bed.

On recovery he consulted, at my request, Dr. A. Ernest Sanson. By permission I quote from letters of Dr. Sanson and the attending physician, Dr. Edwards. The latter says: "Mr. B. came under my care on April 26. He had a very threatening attack of heart failure, with intermittent systole at frequent intervals, often every third or fourth beat. Obvious

evidence of aortic and mitral disease with constant regurgitation at the mitral, and regurgitation at all kinds of pressure on the aortic valves. He has, of course, a heart which is permanently infirm and will at all times be gravely worsened by anxiety, worry or overwork."

Dr. Sanson says: "May 19, 1896. I have to-day examined your patient. . . . I find evidence of hypertrophied left ventricle, some dilatation and hypertrophy of the right chambers, a fusiform dilatation of aorta and abundant signs of obstruction and incompetency at the aortic valve orifice." And later: "February 27, 1898. I can only say that Mr. B. presented the signs of very grave aortic valve disease with consecutive changes in the heart so that the left ventricle had dilated to the production of the systolic murmur of mitral incompetency."

The patient reached home the last of May. Within a week he resumed his business and by the end of September both his systolic murmurs had disappeared, not to return since.

Turning to the tracings in this case, which, unfortunately, were not begun until 1897, Plate B<sup>2</sup> gives two instructive sets of three each. In each set the first tracing is taken just before, the second just after treatment, and the third ten minutes later. The first set is an excellent illustration of immediate tension reduction, shown in the second tracing, and of strong heart reaction in taking up the circulation at a higher tension, as evi-

## Pl. E

denced by the third tracing in comparison with the first. The second set shows less immediate effect from the treatment, yet even here the development of a recoil wave and the elevation of the arterial notch are clearly seen.

Further illustration of immediate tension reduction is given in the first set of Plate B<sup>1</sup>. Here the first tracing shows a very different condition of arterial tension before treatment, bordering on that of mitral regurgitation, and indicates relative arterial contraction and a weak or tired heart action. The immediate effect of treatment, shown in the second tracing, was to dilate the arteries, reducing arterial tension, whereby the systolic wave is accentuated and the unevenness of the ventricular force made apparent in the irregularity of the systolic wave. The full effect of treatment appears in the third, where the heart has again taken up the circulation. The recoil wave, entirely wanting in the first, now shows the firmness with which the ventricle completes the systole, and the arterial wave, carried higher with more uniform curve, shows, as does the lower systolic wave, the restoration of normal tension with a ventricle capable of meeting it.

The last two tracings give an instance of low tension and uneven systole before treatment with recovery of

ventricular force manifest in the first tracing after coming from the cabinet, which means in most cases about five minutes.

The extent of the relief given the heart by twenty minutes' treatment, as manifested in restoration of functional power so plainly shown in these and other tracings, can be no greater surprise to others than it was to myself at first. It is made more believable when we recall that the heart muscle secures its nutrition during the brief periods of diastolic relaxation, and that in pneumatic differentiation both the systolic strain and diastolic stretching, the prime cause of dilatation, are entirely removed.

This patient has taken no drug for his heart during the past nine years, save that on a few occasions, when called upon to make a public address or plead a case before government officials, he has used small prophylactic doses of strophanthus or cactus, unless iron be considered a drug. The effect of pneumatic differentiation on the assimilation of iron, in this case alone, affords conclusive proof of the claims as to its influence on systemic nutrition. During the first seven years of his illness repeated attempts to take iron in daily doses of nine grains of Bland's pill invariably resulted within two or three weeks in such severe headache as to compel their abandonment. Some three or four weeks after beginning treatment by pneumatic differentiation he started with the same amount (9 grains) daily, increas-

## Pl. G

ing to 45 grains per day within two weeks. That amount he has taken for months at a time ever since. During the first few years he never omitted it for more than a week or two, and in all the nine years he has had but one recurrence of the headache, when he had taken this amount for some two months without any cabinet treatment.

We have already explained why the relief can not be as permanent in mitral regurgitation as in the aortic lesion. It is often, however, quite as immediate and decided and as gratefully appreciated by the right as the left ventricle.

CASE E.—Male, 35; uncomplicated mitral regurgitation of rheumatic origin. The tracings in this case (Plate E), by themselves neither suggest cardiac disease nor indicate any particular effect from the treatment. But the pulse rate of 116 and respiration of 30 on the first, tell the story of pulmonary oppression in a way that emphasizes the pulse of 88 and respiration of 24 on the second, a reduction of 28 in the pulse and 6 in respiration, as evidence of what pneumatic differentiation can do for mitral incompetency. Moreover, this reduction with its commensurate subjective relief, was not only maintained until the next treatment, although the patient came from a distance, but was slightly increased by subsequent treatment so that at the end of a month the patient

was considering the resumption of his business as a grocer, when a severe attack of acute rheumatism withdrew him from observation.

CASE G.—Male, 54, had also simple mitral incompetency, although for several years it had been called chronic bronchitis. This patient had suffered for many years from a slowly progressive dyspnea, yet was surprised to learn that he had any heart trouble.

In Case E the tracings show as perfect compensation as is possible with this lesion; but in Plate G the first pair indicate most plainly the stage of force failure, slowing circulation and secondary arterial contraction. The effect of the first treatment is apparent in the second tracing of the first pair only by a slight improvement in the arterial wave, but the reduction of pulse rate from 120 to 96 by this single treatment is quite as striking as in Case E.

Of the second pair, taken five days later, the first compared with the first of the other pair, measures the permanent results gained in this time, unquestionably through improved nutrition, while the second gives evidence in the arterial wave of a slight immediate effect upon tension.

To our mind these tracings from Cases E and G afford conclusive proof of the claims as to the effect of pneumatic differentiation in augmenting blood flow, and the relation of such increase to tissue nutrition and reflex arterial tension.

In summary, therefore, we claim to have shown:

1. From the physical standpoint, (a) that any agent which decreases vascular tension and coincidentally maintains or increases nutrition throughout the entire system, and only such an agent, is an ideal therapeutic measure in organic cardiac disease; (b) that pneumatic differentiation lowers vascular tension, increases blood flow, and coincidentally increases nutrition; (c) that it is applicable to the pathic conditions of valvular lesions.

2. Clinical results prove the accuracy of the foregoing propositions and establish the power of this measure to neutralize the injurious effects of organic cardiac disease more quickly, fully and permanently than can any other known agent.

## ACUTE INTESTINAL OBSTRUCTION.

REPORT OF A RARE CASE OF PROBABLE SYPHILITIC ORIGIN.

CLARENCE L. WHEATON, M.D.

Formerly Assistant to the Clinic Diseases of Women, Chicago Polyclinic; Formerly Attending Physician to the Out-door Free Dispensary, St. Joseph's Hospital, Chicago, and Clinical Associate in Gynecology, Denver College of Medicine.

DENVER, COLO.

No graver condition to which the human subject occasionally falls a victim will ever confront the practitioner of medicine than acute intestinal obstruction. His resources, medical and surgical, will be taxed to their utmost. Should it be the reduction of an invagination, the untwisting of a volvulus, severing adhesive bands, intestinal resection and end-to-end anastomosis, enteroplasty or enterotomy, in fact resorting to any surgical procedure for the relief of the existing condition, the high mortality from all these essentially capital operations renders this subject one well worthy of our consideration.

The usual causes of obstruction in the alimentary canal, while familiar to us all, may with propriety be recalled, as follows: Impaction of fecal matter, foreign bodies in the canal, intussusception, volvulus, constriction by bands usually following a peritonitis, openings in the omentum or mesentery through which the intestine falls and becomes constricted, diverticula, neo-

plasms, stricture and hernia. Grund, Saurel, Soepp and Wyeth have reported cases of obstruction due to lumbricoid worms.

Obstruction due to fecal impaction usually gives the history of a tumor mass slowly appearing: on palpation the mass is freely movable and can be molded between the fingers, the cecum and colon are the usual sites of involvement; in this form of obstruction, the sigmoid flexure follows next in frequency. Obstruction of this type is not usually followed by morbid signs indicative of a serious condition—the vomiting, pain and tenderness on pressure. The accompanying shock so frequently seen in obstruction due to other causes is here usually absent, and if present at all in cases of an extreme degree it is usually one of the last symptoms to appear. This type of obstruction, as would naturally be supposed, is the most amenable to treatment and consequently the least dangerous.

Foreign bodies found in the intestinal tract excluding enteroliths, although they may be the nucleus for enterolith formation, usually gain entrance through the stomach. Dennis quotes the following facts from 51 autopsies: In 33 there was evidence that there had been or that there was a fistula established between the gall-bladder and the duodenum of sufficient size to allow the passage of the stone. In 3 cases the common bile duct had been dilated sufficiently large to admit a finger, there being no fistula present. In one case reported there was a gall-bladder stomach fistula, and in one a gall-bladder colon fistula.

The exact location of the impacted calculus has been determined in 83 cases, showing the lower ileum involved 50 times and the jejunum 13 times.

Intussusception or the telescoping of one portion of the bowel into another is usually met with in infancy.

Holt reported 385 cases under three years of age, 28 under four months, 113 between four and six months, 71 between seven and nine months, 18 between ten and twelve months, 32 between one and two years, 96 between two and ten years. Three-fourths of all the cases reported occurred in children during the first two years of life.

Bands of cicatricial tissue following an acute or chronic peritonitis are at times predisposing if not active etiologic factors in obstruction.

Hernia excepted, obstruction by cords and bands is the most frequent of all types; 35 per cent. of Leichtenstern's cases were of this type. Malignant growths, while they ultimately result in acute obstruction, are the most frequent cause of the so-called chronic type of obstruction. Columnar-celled carcinoma is pathologically the type of cancer met with; sarcoma, while uncommon, has been found in the small intestine.

Bessel Hagen reported a case of primary sarcoma involving the jejunum. Jalland reported a case of sarcoma of the small intestine; Modling collected 14 cases. Cancerous strictures are frequently situated at the sigmoid flexure, next in frequency at the ileo-cecal valve and rarely at the splenic and hepatic flexures.

Leichtenstern, in 1134 hospital cases excluding hernia and malignant diseases, has shown that one death in every three, or 500 cases, is due to intestinal obstruction in some form. Fagge in 4000 autopsies reports 54 deaths from intestinal obstruction.

True intestinal concretions, according to Leichtenstern, occur in less than 2 per cent. of cases; in 1153 cases of obstruction he found 41 caused by gallstones. Courvoisier reported 131 cases of obstruction from this

cause, Trever 30, and Wisnig 50. Dennis reported 149 cases of intestinal obstruction due to gallstones and enteroliths, of which 133 were the former and 16 the latter.

In the pre-anesthetic days the mortality in operation for the relief of intestinal obstruction is quoted at 75 per cent.; since the days of anesthesia Senn quotes the mortality at 58 per cent.

Curtis reported 328 cases operated since 1873 with a mortality of 68 per cent.; 101 cases were operated with the patient moribund. In 45 of Curtis' cases there was excision and suture with a mortality of 86 per cent.; in 190 cases in which the constriction was merely relieved he reported a mortality of 57 per cent.

The treatment, except in some cases of intussusception and of fecal impaction, is purely surgical and needs no discussion here.

From the somewhat extensive perusal of the literature I am unable to find any reports of cases similar to the one herewith presented, which occurred recently in my practice. The unexpected complication and the non-malignant nature of the growth found at the sigmoid flexure make the case one of interest.

I was called in consultation with Dr. W. L. Keller, of the Army, to see Mrs. H., aged 31. She complained of pain and tenderness over entire abdomen; menstruation was profuse and irregular; nausea and vomiting present to a slight degree; temperature at time of first examination was 99, pulse small and with little tension.

On inspection the face presented a somewhat drawn and anxious expression; abdomen was slightly distended and tympanitic. On palpation a tumor mass the size of a child's head could be easily outlined, at a point corresponding to the fundus of the uterus. Vaginal examination revealed the presence of a mass occupying the pelvic outlet and well down in the vagina. Diagnosis: myomata of uterus. The patient was referred to hospital for operation, and Dr. W. A. Jayne, of Denver, was called in consultation. After 24 hours in the hospital the patient said that her bowels had not moved for six days, and that previous to this time her evacuations had been scanty. There was no previous history of diarrhea; cathartics were freely resorted to in our efforts to move the bowels. Thirty-six hours after entrance to the hospital the abdomen became markedly distended and tympanitic; colicky pain and tenderness existed over entire abdomen; nausea and vomiting now became a prominent symptom and the vomiting so pronounced that everything taken into stomach was rejected. Repeated high enemas failed to move bowels.

The diagnosis of complete obstruction was made and the patient operated on by Dr. Jayne and myself. Median abdominal incision was made. The intestines were enormously distended with gas, and only after numerous punctures to eliminate the gas could they be manipulated. A thin serous fluid escaped from the peritoneal cavity, the walls of the intestines were acutely inflamed and there was every evidence of a beginning peritonitis. The myoma of the uterus was plainly visible. At the site of the sigmoid there was a mass about  $3\frac{1}{4} \times 2$  inches, which involved the gut and produced complete occlusion of its lumen.

The tumor was with difficulty resected, owing to the extensive adhesions to surrounding structures. End-to-end anastomosis performed by means of Murphy's button; the abdomen was then closed in the usual manner. Forty-eight hours after operation the patient died; postmortem examination revealed the presence of a leak at the site of button.

The pathological examination of specimen as given by Dr. Wilder, pathologist to St. Luke's Hospital, is as follows: Sections made from the tumor of sigmoid flexure, which was submitted for examination, show the growth to consist entirely of a mass of rather dense fibrous tissue containing a few blood vessels. The latter having well developed walls. I find no evidence of either tubercle or of malignant changes.

## MODIFIED TREATMENT OF TYPHOID FEVER.

T. B. GREENLEY, M.D.

MEADOW LAWN, KY.

The treatment of typhoid fever might be termed a hackneyed subject, but as it is a prevalent disease in many sections of the country, and there seems to be no settled mode of treatment, I regarded myself at liberty to try something new in its management. As it is usually a protracted disease, anything that we can use safely in its treatment, by which its extent can be shortened, I regard as legitimate.

Some say: Treat the patient instead of the disease, while others say: Watch and treat symptoms as they arise; others again contend that diet is the main thing in its control. I am of the opinion that we must, to some extent, pay attention to all these considerations, and at the same time not neglect the mind and pleasant surroundings.

As far as I am individually concerned, I have had but few cases of the disease coming under my control for several years. The plan of treatment I have recently adopted, as it pertains to therapeutics, has been confined to only some three cases of recent occurrence. The first and third of these cases were very short in duration, only continuing eight days from the time I first saw them. The third patient had been complaining about a week, and his father, thinking he had malaria, had given him quinin and laxatives. The second case was of longer duration, partly due to neglect in the way of nursing as well as diet. When called to see this patient I found him alone in his room, and had to get some of the neighbors to attend him and give the medicine. He had poor attention during his illness.

In these cases, when the fever was above 102 F., I increased the quantity of medicine, say one grain each of quinin and acetanilid, but did not shorten the intervals; but when the patient was asleep and resting quietly, I prolonged the intervals of giving the medicine. I regard rest, quietude and sleep of great advantage in the treatment of typhoid fever. This is why I dislike the Woodbridge plan of frequent doses.

Should the temperature resist antipyretic effects of the medicine I have the surface sponged with tepid water, which is quite soothing to the patient and keeps the skin in good condition. It is more convenient and more pleasant than the cold bath.

It has been a rule with me for many years, in the treatment of typhoid fever, to administer small doses of turpentine in cases troubled with tympanites. It not only relieves the tension of the bowels by expelling the gas, but acts as an antiseptic. I have had little trouble with diarrhea in this disease for years, and entertain the opinion that turpentine acts as a preventive. Another benefit we may derive from the use of turpentine is its prophylactic action against hemorrhage, either from the nose or bowels.

I am greatly in favor of milk, given as patients call for it, but in some cases it may be necessary to urge them to take it. I also allow them to have oatmeal mush, with sugar and cream, several times a day. Now and then we find a patient who dislikes sweet milk, but prefers buttermilk, freshly churned. I find no objections to the latter, as it contains the same elements as the sweet milk that has been skimmed; they both contain the fat and muscle-making principles, namely, hydrocarbon and casein. Should sweet milk curd on the stomach, a little soda or lime water will prevent it.

Milk may, by way of change, be alternated with soups of different kinds. It is very essential, in the

convalescent stage of the disease, to watch the patient, both as to diet and muscular over-exertion. I have lost some three patients from imprudence in these particulars after they were dismissed.

One reason why I think quinin a proper remedy in the present type of typhoid fever is the fact that it occurs during the malarial season of the year. When I commenced the practice of medicine in 1845, and up to 1875 I only met with winter and spring typhoid, and did not think it necessary to give quinin. The first case of summer or fall typhoid I ever saw was in the fall of 1875, when I had an introduction to it of six cases at the same house. They fortunately all recovered. The old-time winter typhoid was generally attended with symptomatic eruption. We also expected a week or ten days of what is called the nervous stage.

In the fall and summer typhoid fever, we usually find the pulse much slower than it was in the old winter typhoid, as well as in remittent fever. This is one of the distinctive characteristics of identity between the summer or fall typhoid and the latter disease.

My reason for the use of acetanilid with quinin is that it has a soothing and quieting effect and prevents the possible irritating effects of the latter on the nervous system. It also, to some extent, acts as an antipyretic. I have not observed any depressing effects of acetanilid on the heart. It is always well to increase or diminish the dose according to amount of temperature.

#### MEDICATION OF THE RESPIRATORY TRACT BY ANTISEPTIC NEBULÆ.

HOMER M. THOMAS, A.M., M.D.

CHICAGO.

The antiseptic value of nebulae in the treatment of diseases of the respiratory tract is well recognized by the profession. How to administer them in sufficient strength and quantity to control respiratory septic processes has been the problem. If administered by the stomach in suitable strength and quantity to sufficiently saturate the lungs, as a rule the stomach and lower alimentary tract is so irritated that digestive functions are greatly deranged, hence Nature's method of controlling these processes by vital resistance is much impaired; if introduced directly into the lungs by a parenchymatous injection, so much irritation is produced that an exudate is thrown out which occludes the finer air passages and prevents the introduction of the medicaments; therefore, the normal method of reaching these septic processes is by combining in a respirable form antiseptic nebulae.

There are many mechanical methods for the introduction of antiseptic nebulae into the respiratory passages. These vary from the single hand-bulb nebulizer on up to the elaborate mechanisms found in the efficiently equipped offices of the modern medical men. The problem in this form of treatment has been to provide an efficient mechanism for home treatment by patients. For, with the thorough measures of treatment instituted in our offices to be supplemented by the patient's home use of remedies under the guidance of the physician is to reach the most effective results from this form of treatment.

In this connection I may state that I have found a new device, Benson's Home Nebulizer, very satisfactory for the individual use of patients. The accompanying cut makes any extended description unnecessary. This apparatus is compact, portable, inexpensive, and of considerable capacity for complete lung inflation. Its practi-

cally steady current of compressed air is filtered and antiseptized before performing its nebulizing duties proper.

As to the formulae valuable for use in antiseptic nebulae, the experience of the physician as to the specific case must necessarily be determined largely by his own judgment.

My personal preference has been in favor of simpler rather than complex mixtures. I seldom combine more than one antiseptic in a given mixture. The best vehicle with which to combine an antiseptic is the commercial preparations of the liquid hydrocarbons. In a 4-ounce mixture of oleum petrolati I frequently add 30 drops of the chemically pure oil of wintergreen, for use in cases of slight catarrhal bronchitis. Merck's oil of cloves in the proportion of 40 drops to 4 ounces of the vehicle is very useful in cases of subacute bronchitis. One of the most delightful as well as soothing nebulae consists of the imported chemically pure oil of pine needles in the proportion of 50 drops to 4 ounces of the vehicle where there exists acute catarrhal coryza of the respiratory tract.

The above will readily suggest to the physician the general scope and character of the large number of remedial agencies from which to choose. Formulae contain-

ing cocain muriate with gum camphor will do much toward allaying the discomfort in tonsillitis. Mixtures can be made up containing iodine crystals, beechwood creosote and oil of tar for laryngeal and pulmonary tuberculosis, and so on through the wide range of efficient antiseptics at our command. I believe the chances of successfully coping with respiratory disease are greatly enhanced by general adoption of the inhalation method.

**Trauma in the Etiology of Infectious Cerebral Affections.**—Ehrnrooth of Helsingfors had occasion to treat two cases of infectious brain affections which developed consecutive to a contusion of the skull, without solution of continuity. He produced a similar contusion on the skulls of 167 rabbits, and inoculated 90 with streptococci, 16 with staphylococci and 11 with pneumococci. More than 63 per cent. of those inoculated with the pneumococci, 56 of those inoculated with staphylococci and 54 per cent. of those inoculated with streptococci died with evidences of an infectious process in the brain. Of the 50 animals infected, but without trauma, only 9 showed traces of an infectious process in the brain. The contusion therefore must have afforded a favorable place for the colonization of the bacteria in the blood, even in the absence of any lesion of the skin or meninges.—*Nord. Med. ## SYMPTOMATOLOGY OF LESIONS OF THE PREFRONTAL LOBE.

The diagnosis of tumor of the brain may be easy or difficult, in accordance with the situation and the mode of growth of the neoplasm. The difficulties are greatest when it is situated in the so-called silent or latent areas of the brain, but invasion even of these often gives rise, as increasing experience is showing, to characteristic symptoms, whose significance we are only beginning to appreciate. This is particularly true of the prefrontal lobe, lesions of which, while usually unattended with motor manifestations, give rise to peculiar mental disturbances. These consist in loss of self-control and a subsequent change in character, with errors in judgment and reasoning. There is inability to fix the attention, to follow a continuous train of thought or to conduct intellectual processes. Sometimes also the gait is staggering, like that of cerebellar disease.

A case illustrating the localizing value of the symptom-complex under consideration and in which operation was successfully undertaken by reason of the correctness of the diagnosis is recorded by Drs. William Elder and Alex Miles.<sup>1</sup> The patient was a man, 47 years old, who five months before the coming under observation began to suffer from pain, at first in the back of the head, but soon afterward referred to the left frontal region, where it subsequently remained localized. Early in the illness the left side of the forehead and face became swollen to such an extent as to close the left eye and during the continuance of this swelling the pain in the head was lessened. After about four weeks, while the patient was taking some medicine, probably potassium iodid, the swelling began to disappear gradually. Vomiting of cerebral type—without relation to food or other apparent cause—took place occasionally.

In the further progress of the case the patient became depressed, refused to leave his bed and would not speak to his wife. He sometimes refused to take food, although his appetite appeared to be normal. His memory became impaired, especially for recent events. He became unduly emotional and wept on slight provocation. He seemed to lose all sense of decency and shame, exposing his person unduly and needlessly. He suffered from incontinence of urine and later also from rectal incontinence, not apparently because of weakness of the sphincters, but from a loss of the sense of propriety.

At times he failed to recognize his surroundings. There was now marked pain in the left frontal region and a swelling appeared over the left frontal eminence.

On admission to the hospital the man was found to be sleepy, dull and apathetic, and he could be roused only with difficulty by pricking or shaking or a sharp question. When awakened, he yawned frequently. Hearing seemed to be normal. Responses to questions were correctly expressed, but were made more slowly than normal. The patient was unable to sustain his attention for any length of time. Lack of judgment was a marked feature of the mental condition. There was no aphasia, but a slight degree of dysarthria. There was slight paresis of the lower part of the right side of the face and the right upper extremity. The plantar and patellar reflexes were preserved, but not exaggerated, although there was ankle clonus. The man walked without difficulty, and co-ordination appeared preserved, although the wife stated that he staggered on suddenly getting up out of bed, but he did not complain of giddiness. There was for a time no pain in the left frontal region unless the skull were percussed, but later tenderness on pressure was appreciable over the small round swelling in this situation, which evidently arose from the bone and was soft at the center. In the right frontal region was a small depressed cicatrix resulting from an abscess that had been opened three years previously and had followed a blow in that situation four years earlier. Examination of the blood disclosed a slight reduction in the number of red corpuscles and in the percentage of hemoglobin, but no increase in the number of leucocytes. The left eye had been disorganized by smallpox and vision in it was completely wanting. In the right eye vision was still good, and the pupil was slightly contracted, although it reacted to light. On ophthalmoscopic examination the fundus of this eye exhibited some blurring of the edges of the disc, with some dilatation of the veins. No history of syphilis could be obtained, although the wife had had three miscarriages and had borne four living children.

The condition of the patient grew progressively worse, despite active treatment with mercury and iodine. The presence of a new growth being suspected, operation was undertaken. A small area of caries was found on the surface of the left frontal eminence, which was separated from the scalp by cheesy debris. On introducing a finger, after removal of a disc of bone and incising the dura mater, a firm nodular mass was detected occupying the tip of the frontal lobe. This proved to be a definitely circumscribed tumor, with a thin covering of cortex. It was easily shelled out, without causing hemorrhage, and the cavity left was immediately filled by bulging brain-tissue. The wound was closed and the patient progressed to speedy recovery. The growth presented the histologic structure of a syphiloma.

This case is an admirable illustration of the precision in diagnosis that can be attained by careful study of

1. Lancet, February 8, p. 203.

symptoms and history and of the successful results that can be accomplished by prompt and intelligent surgical intervention. The number of cases in which a like result has been obtained is not large, principally because even when a new-growth is correctly diagnosed and located it is often so situated as to be insusceptible of removal.

#### ARSENIC AS A NORMAL CONSTITUENT OF TISSUES.

Gautier's discovery that minute quantities of arsenic can be detected in perfectly normal tissues of human beings who have not taken arsenic knowingly, has attracted much attention, especially because of the short time that had elapsed since Baumann's discovery of iodine in the thyroid. The interesting deductions that Gautier made, also did much to arrest attention. Briefly, Gautier's<sup>1</sup> results were as follows: By using 100 grams or more of the substance to be tested minute quantities of arsenic could be detected in many tissues. The thyroid gland contained the most, about 0.75 milligram per 100 grams. Next to that came the mammary gland, with 0.13 mg. The brain contains variable quantities, usually more than the thymus, which in turn contains more than the skin and its appendages in which traces are constant. A great many other tissues that were examined showed no arsenic, among which was the hypophysis, strangely enough considering its relation to the thyroid. This arsenic seemed to exist along with iodine in the nucleo-proteid of the thyroid; perhaps substituted for phosphorus in this proteid.

There is so little arsenic in the tissues that it is not of medicolegal importance, especially since it could not be found in the large organs that generally are examined. Even if decomposition should cause the arsenic of the thyroid and skin to be dispersed throughout the body the amount would still be too small to be detected.

But most interesting of all Gautier's results, was the finding of a considerable amount of arsenic in menstrual blood. An average of 0.28 mg. of arsenic was found per kilogram of blood, from five healthy women. Gautier points to the fact that the total amount of arsenic eliminated in this way corresponds quite closely to the amount he found in the normal thyroid. This led to an examination of menstrual blood by Bourelet for iodine, which he found present in the proportion of 0.90 mg. per kilogram, whereas normal blood contains but .025 mg. The evident relation between the thyroid and sexual functions being well known, Gautier considers these findings as corroborative of his assumption of a relation between iodine proteid and arsenic proteid. The great loss of arsenic that thus occurs monthly led him into remarkable channels of speculation. He had found no arsenic in the ordinary excretions, although it was obviously being ingested both in proteid foods and also in certain vegetables which have been shown to contain this element. Therefore, he concluded that the normal channel of elimination was by the desquamation of

the superficial epidermis and the loss of dermal appendages. By a characteristically Gallic fitting into comparative anatomy, physiology and psychology he arrives at these striking conclusions: Arsenic nucleo-proteid ordinarily goes to supply material and stimulus for growth of the skin and its appendages. In the female during menstruation it is diverted to the organs of generation where it provides for the development of fetal tissues if impregnation has occurred, or else is cast off in the menstrual blood. It is because of this disposal of the arsenic that in the female the hair ceases to be produced after puberty. The male not losing his arsenic in this way continues to grow hair, and removes his arsenic by cutting the hair, shaving, and desquamating! He cites instances among lower animals in which the hair or feathers or corresponding dermal growths increase until the season of rut, then the arsenic being diverted to the generative organs the nourishment of these appendages is lowered and they are cast off, or molted.

In fact, Gautier's train of logic is so pleasing, his comparisons so apt, that it is with a feeling akin to regret that one learns that Cerny,<sup>2</sup> who has repeated part of Gautier's work, has failed to corroborate it completely. Cerny found only most minute traces of arsenic, at most .01 mg. per kilogram, in the thyroid, and that not constantly. Furthermore, he found almost as much in the liver, where Gautier did not find any. He states that the presence of these minimal amounts of arsenic is not surprising, in view of the wide distribution of arsenic in nature, and the general use of arsenic in the industries. He concludes that the amount of arsenic is too small and too inconstant to play any physiologic rôle, and is at a loss to explain the differences between his results and those of the French observer.

#### ETIOLOGY OF CARCINOMA.

Fuetterer deals interestingly, in an original article in this issue, with one phase of the cancer question, namely, the frequency with which benign ulcers of the stomach are transformed into carcinomata. Moreover, he believes that such change may take place in small and recent ulcers as well as in large chronic ones, and cites instances. Furthermore, he thinks that the degenerative changes first occur in the edges of the ulcer, rather than at its base. There is no doubt, as he says, that the constant irritation to which gastric ulcers are exposed, especially those near the pylorus, strongly predisposes them to undergo malignant degeneration. This is an important statement, and is undoubtedly true; since, according to the best authorities, practically three-fourths of all gastric ulcers are at or near the pylorus, occupying the constricted segment of the stomach rather than its expanded portion, or larger segment. So careful a man as Hauser estimated that 6 per cent. of gastric ulcers ultimately became carcinomata, and many others have taken a far more pessi-

1. *Comptes Rendus, Académie des Sciences*, Tome 129, 130, 131.

2. *Zeit. f. Physiol. Chemie*, 1902, xxxiv, 408.

mistic view of the possibilities; Doyen, for instance. Even the optimistic Leube maintains that if medical treatment of gastric ulcer has failed after four or five weeks' trial, it is not likely to be successful. Kocher agrees with this opinion, and therefore rightly insists, from the surgeon's standpoint, that such cases should be promptly operated on. Chronicity, especially in those past 40, is to be looked upon with suspicion, for it may indicate incipient carcinoma. Now, that gastric ulcer is generally regarded as a disease that may be operable on account of adhesions, hemorrhage, perforation, cancerous change, etc., more accurate information concerning it will soon be forthcoming. There can, however, be little doubt that the stomach is sharing in the gain made by carcinoma in its encroachments upon all organs and portions of the body. It has fortunately been shown by Mayo Robson, William Mayo, W. W. Keen, and others, that the stomach is very tolerant of operative interference, and is an especially inviting field to surgeons. The cases reported and collected by Fuetterer call attention to this fact, perhaps the most important one in connection with gastric ulcer, that chronicity or failure to heal promptly, under suitable medical treatment, should be met by consultation with a modern surgeon fully alive to the possibilities of judicious surgery. Partial gastrectomy is a comparatively safe procedure, as was shown by Rodman, who collected all such cases operated on prior to 1900 and reported them in a paper read before the American Surgical Association at Washington. Eighty-five per cent. of pylorectomies, partial gastrectomies or excisions recovered fully. If we exclude cases operated on prior to the past decennium—before the perfection of aseptic technique—the mortality is materially lessened.

That gastric ulcers not infrequently undergo malignancy, is additional evidence in support of the theory of mechanical irritation, so largely adopted by authors as the chief etiological factor in producing carcinoma. It will be found that throughout the gastro-intestinal tract that points of constriction, irritation or both, as the lips, tongue, esophagus, cardia, pylorus, ileocecal valve, appendix and rectum, most frequently suffer from carcinomata. Such is also true of the external parts and organs, as the mammary gland, penis, scrotum of chimney sweeps, and arms of workers in paraffin. Such a cause may, it is true, only pave the way and prepare the soil for a germ which comes later, and finds tissues with their normal physiological resistance diminished, as is maintained by the adherents to the germ theory of carcinoma. There is much in the life history of carcinoma, its encroachments racial and geographic, its persistence in certain districts, localities, even certain houses, to strongly suggest a probable germ as its cause. Attractive as the theory of the parasitic origin of cancer is, it can not be said in fairness that a majority of authors or careful observers accept such teaching. The work of Gaylord and others, though commendable, is not conclusive.

While fully agreeing with Fuetterer and others who maintain that gastric ulcers undergo malignant transformation in a certain if not a large percentage of cases, still it is easy to be mistaken, and, therefore, one can not always conclude that a condition of malignancy exists because there are found adhesions, enlarged lymphatic glands, etc., at the time of operation. So good a man as Bidwell twice made such a mistake; thinking his cases cancerous he performed gastro-enterostomy as a palliative procedure and was surprised to find that both cases recovered fully and abidingly, the enlarged glands being evidently inflammatory in character. A large percentage of the cases of gastric ulcer thus far excised presented a condition closely resembling malignant disease. In separating adhesions, for instance, such surgeons as Billroth, Hofmeister, Klausner and Krogus have torn into the stomach, so great were the difficulties.

#### SOME INTERESTING QUESTIONS IN MALARIA.

The problems of malaria are not yet all solved by the recent advances in our knowledge regarding it. We know the parasite and in a general way its life history, and more important still we know how it is introduced into the human organism and how to avoid it. There are still, however, the puzzling facts of immunity and other questions that require solution. A suggestive article<sup>1</sup> has recently appeared from the pen of Dr. A. F. A. King, who it will be remembered was one of the earliest advocates of the theory of the agency of the mosquito in the transmission of malaria. In this recent paper he adduces facts that seem to him to indicate that the growth of the plasmodium in the blood is influenced by light. Among these are the infrequency of malarial paroxysms in the night hours, the relative immunity of the dark-skinned races, the favoring influence of bright sunny weather as opposed to cloudy weather on the occurrence of the attacks, the popular notion that shade prevents the attacks, and the fact that red light stimulates amebic growth, and that light transmitted through the blood must necessarily be red. The therapeutic suggestions, based on these ideas, are the keeping malarial patients in the dark, or deprived of red light; the use of white clothing with opaque black or purple linings, in the tropics, and the employment of drugs that darken the blood or lessen its translucency. If the rays from the violet end of the spectrum inhibit the growth and propagation of the malarial parasite, the use of Prussian blue (an old remedy) and more lately of methylene blue is explainable. Dr. King suggests that the fluorescent action of quinin intensifying the violet may explain its hitherto enigmatical specific action in malaria. Another vegetable product having this property is esculin and this has also been successfully employed as an antiperiodic. The paper is ingenious and suggestive rather than conclusive, but it deserves a place in the literature of malaria. Possibly the line of investigation it points out may be a profitable one and may add something of value to our knowledge of the pathologic conditions of malaria as well as to the resources for their prevention.

1. Am. Jour. Med. Sciences, February, 1902, p. 221.

## DANGER OF INFECTION FROM CIGAR CLIPPERS.

In these days of general microbiphobia, new perils to health and life are constantly unfolding themselves before our troubled visions. Some of these as given out are without question exaggerated and comparatively negligible; others, however, are worthy of some attention. The dangers from certain methods sometimes employed by cigar-makers were recognized long ago, even before the popular fear of germs had been aroused. The latest danger from this source is indicated, according to the newspapers, in a warning of the Chicago Board of Health, which pronounces the "mechanical cigar-clippers" in general use where cigars are sold a menace to the health of the community. It is a common practice for a smoker to moisten the tip of his cigar with saliva before inserting it into the clipping machine; he thus leaves whatever pathogenic germs his mouth can convey to infect the next comer. A continual series of such procedures can, it is easily imagined, make these little conveniences excessively dangerous disease-promoters. The most obvious and serious peril would, of course, be from venereal disease. A saloon frequenter with his mouth well supplied with mucous patches could be readily conceived to be a very effective disseminator of his disease, and without doubt some of the cases of extra-genital syphilis have originated in this way. There is a still further danger to be considered; the infected clippings are not thrown away or destroyed, but serve, at least in many cases, to meet the demand for tobacco in some other form, as cigaret and snuff material, which are other agents for spreading infection. Our pleasant vices are our scourges often enough, and it would be well that the malign possibilities of even the comparatively innocent habit of tobacco indulgence should be known and so far as possible avoided. If smokers would only employ their own clippers, even the primitive ones furnished by nature, they would escape at least one possible peril of the present day.

## OCULAR DEFECTS AND HEADACHE.

Ophthalmologists probably sometimes magnify the effects produced by ocular errors of refraction, but it is certainly true that such refractive defects are responsible for a large proportion of headaches and for other reflex disturbances. In a recent article<sup>1</sup> George S. Hall of California states that very many of the neurasthenics who go across the continent in search of health have errors of refraction, which are the largest factor in their breakdowns, and he finds that a pair of spectacles often does what the climate will not for such persons. He also insists upon the deleterious effects of such defective eyes upon the general health of tuberculous patients. In opening the discussion upon headaches and their treatment at the 67th annual meeting of the British Medical Association, Landner Brunton<sup>2</sup> said: "In all cases of headache the first thing to do is to examine the teeth and see if any are decayed; next the eyes and see if there be any abnormality in them. The most common cause of headache is certainly some abnormality in the eyes." He considers two factors to be active

in the production of headache: 1. a general condition with disordered or imperfect nutrition; 2. a local condition. The former condition renders the person liable to pain, the latter determines the location of the pain, and this determining factor is most often decayed teeth or defective eyes. In neurasthenic patients the general conditions are such that headaches may result from errors of refraction which in health would have caused no trouble. Such a headache, once established, may in itself further disturb the nervous equilibrium of the patient. In this class of cases the good effects of properly adjusted glasses, by relieving the patient of a disagreeable symptom, may be very great. This "ocular headache" must not be confused with the "neurasthenic headache," which is possibly toxic in origin and continues after every source of peripheral irritation has been removed. Neurasthenic headache is very intractable to treatment by drugs and a suitable climatic condition is of much value in bringing about a cure. In tuberculous patients ocular headaches may have a bad influence upon the general condition. The pain and discomfort bring about a depressed mental condition and there follows loss of appetite and indisposition to go out of doors with resulting bad effect upon the general health. A routine examination of the eyes of all neurasthenic patients is to be recommended, and in cases of chronic disease where ocular defects may be the cause of headache and other disturbances which have an unfavorable influence upon the patients, the possibility of learning something by the examination of the eyes which may be of value should not be forgotten.

## HOSPITALS FOR THE INSANE.

As the gloom of ignorance surrounding the nature of insanity has been gradually dissipated by the light of accumulating knowledge, more rational methods of treatment have found their way into practice. Insanity is no longer looked upon as a supernatural visitation, from which there is no escape and for which there is no preventive or remedy, but rather as a morbid state comparable to other disordered conditions of the body, having similar underlying causes and therefore amenable to analogous therapeutic measures. It is this modern scientific view that is responsible for the improvements in the treatment of the insane witnessed during the latter half of the century just ended. No longer is it deemed necessary to incarcerate such a patient and condemn him to a life of hopeless isolation and inactivity. Far more is to be gained, as a constantly increasing experience teaches, by placing him amid congenial surroundings, with only such restraint as to protect him from harm; by ministering to his wants in the same way as those of one ill from any other disease are attended to; and so soon as he is convalescent, by encouraging him to take such exercise and engage in such pursuits as are likely to contribute most to his well-being and increase his usefulness. In the same spirit the designation "Hospital for the Insane" has gradually replaced that of "Asylum," and a step further in progress in this direction has been taken by the board of trustees of the Butler Hospital at Providence, R. I., who, upon the suggestion of their far-seeing phy-

1. The Ophthalmic Record, January, 1902, 27.

2. British Medical Journal, Nov. 4, 1899, 1241.

sician and superintendent, Dr. G. Alden Blumer, have decided to eliminate wholly from their official title the words "for the insane." As is properly pointed out in the last report of the hospital just issued, although the institution is devoted to the treatment of one special form of disease, this is not so distinct from other forms, either in etiology or in symptomatology, as is ordinarily believed. The institution aims to be truly a hospital and not merely a place of confinement or detention for irresponsible persons. There still exists among many people a notion that there is attached to those who are so unfortunate as to suffer from insanity some stigma that is accentuated by residence and treatment in a hospital, just as there lingers in some remote quarters a prejudice toward hospitals in general. The enlightened action of the trustees of the Butler Hospital can not be too highly commended and is deserving of general imitation. This would go far to correct the false views that exist in this connection and would give an impetus to the institutional treatment of cases of the kind at the earliest possible moment, for it must be admitted that, while in the abstract, there may be reasons why it would be desirable to conduct the treatment at home, few families can provide the facilities and the resources that are at command in a well equipped hospital.

## Medical News.

### ILLINOIS.

**Dr. Shepard Promoted.**—Dr. John L. Shepard, of Illinois, acting assistant surgeon, U. S. Army, has been made first lieutenant and assistant surgeon in the regular establishment.

**Jacksonville Physicians Deplore Fenger's Death.**—At a recent meeting of the Jacksonville Physicians' Club the following resolution was passed: Resolved, That, in the death of Dr. Christian Fenger, of Chicago, the medical profession has lost a member whom it delighted to honor; one whose work, like his life, was confined to no one land or tongue, but was as cosmopolitan as the fraternity he honored with his name; a great surgeon, pathologist and teacher; one of whom it might fittingly be written: *Doctores docuit*.

**Disagreement in Marshall Case.**—It looks as if Dr. James A. Marshall were to be made a political scapegoat. After a long trial, the board of managers of the Illinois State Reformatory, Pontiac, has passed the following resolutions:

WHEREAS, The board of managers of the Illinois State Reformatory as now constituted is unable to agree on a verdict in the matter of the investigation of the charges against Dr. James A. Marshall, and

WHEREAS, There is a vacancy existing on said board; therefore, be it

Resolved, That the president of said board be authorized to cite the said Dr. Marshall to a new hearing, and further

Resolved, That it is the desire of the board that the governor fill said vacancy.

### Chicago.

**Prevalence of Pneumonia.**—Laboratory examinations show increasing numbers of the pneumococcus, and there is reason to apprehend another increase of this disease.

**The Hospital of the Holy Family of Nazareth** has given a trust deed to secure a loan of \$50,000 for five years. The building is nearing completion and will have cost, when completed, about \$400,000.

**Honor for Dr. Murphy.**—The Lactare medal, the highest honor in the gift of the University of Notre Dame and perhaps the most highly-prized honor that can be attained by a Catholic layman in America, has been conferred this year on Dr. John B. Murphy, of Chicago, in recognition of his merit as a Christian gentleman and his great work in medical science.

**Hospital for Women.**—The lay press announces that at a meeting of the alumnae of the Northwestern University Woman's Medical School, it was decided to establish a hospital to perpetuate the memory of the school. The new hospital will

be entirely under the management of alumnae of the school. It is stated that no man can enter this hospital except as guest, janitor or patient. Among those who are taking an active part in the planning of the new hospital are Drs. Sarah Hackett Stevenson, Eliza H. Root, Effa V. Davis and Mary J. Kearsley.

**Last Week's Mortality.**—Last week's death rate, says the Health Department Bulletin, fell to nearly the normal for the season of the year. The 514 deaths recorded—120 fewer than during the previous week—furnish an annual rate of 14.72 per 1000, instead of 18.15 of the week ended March 1. This is a decrease of 18.8 per cent. and is only 4 per cent. higher than that of the corresponding week of last year. Except diphtheria, all the principal causes of death show a marked reduction. There is a 12.5 per cent. increase of diphtheria mortality since February 1 over the January mortality this year, and the commissioner is making increased effort to secure the prompt and more general use of the diphtheria antitoxin on this account.

### MARYLAND.

**Vital Statistics.**—For the week ended March 8 the deaths in Baltimore were only 192 against 230 the previous week. Pneumonia caused 21 and consumption 23 deaths. The births were 356, the disproportion being accounted for by the fact that most physicians report births only at the end of the month.

**For Cambridge Hospitals.**—A delegation of citizens from Dorchester and other counties of the eastern shore is asking for the Cambridge Hospital an appropriation of \$4000 a year, and also an additional appropriation of \$5000 to be used in conjunction with a similar amount which has been agreed on by the County Commissioners, for the construction of a new building.

**Appropriations for Medical Colleges.**—A bill has been introduced in the legislature appropriating \$15,000 annually for two years to be equally divided between the Baltimore Medical College, the University of Maryland and the College of Physicians and Surgeons. The Board of State Aid and Charities has strongly advised against such appropriations, and a fight over it is in prospect.

### Baltimore.

**Personals.**—Dr. William Lee Howard will go abroad in May and spend most of the summer in Portugal.—Dr. Frank W. Smith has resigned as resident physician of the Hebrew Hospital and will enter in practice in Highlandtown, a water suburb of Baltimore.—Dr. Edward M. Schindel has been unanimously nominated for a third term for mayor of Hagerstown by the Democratic city convention.—Dr. Robert H. Goldsmith, president of the Alumni Association of the University of Maryland, celebrated, on March 9, the semi-centennial of his graduation in medicine.

**Frick Library.**—The Report of the Frick Library of the medical and chirurgical faculty shows 1936 volumes in the collection. A large proportion of these are standard works and important recent monographs on medicine and the allied specialties. Particular care has been taken to keep up to date the section on urinary diseases in which Dr. Charles Frick was so greatly interested. The special collection of works on biography and on the history of medicine has been much appreciated; 243 volumes were added during the year; 100 volumes of rare old books were purchased by Dr. Osler in Amsterdam and Edinburgh and presented to the library. There were 3771 readers in the room, and 1898 volumes were borrowed for home use. A case has been purchased to hold the books which were in the personal library of Dr. Frick, and this has been placed below his memorial tablet. Subscriptions were received as follows during the year: Mr. W. F. Frick, \$500; Dr. William Osler, \$200; Mr. Frank Frick, \$50.

### MISSOURI.

**Crossland Banquet.**—A banquet is to be given Dr. John R. A. Crossland, St. Joseph, who will soon leave for Liberia.

**Physicians Dined.**—The St. Louis Medical Society entertained Drs. William T. Corlett of Cleveland and Dr. Alambert W. Brayton of Indianapolis at dinner, March 1. After dinner these gentlemen addressed the Society on "Smallpox."

**Gregory Testimonial Banquet.**—Arrangements are being rapidly completed for the Gregory banquet to be held in St. Louis on April 17. Governor Dockery, of Missouri, who is a physician and a student of Dr. Gregory, will preside over the banquet. Every indication points to a large attendance.

**Central Medical College, St. Joseph,** held its commencement exercises, March 1, graduating a class of ten, including two

women. The faculty address was delivered by Dr. W. L. Kenney; the address to the graduates by Hon. Benjamin J. Castiel, and the degrees were conferred by Dr. Moritz F. Weymann.

#### NEW YORK.

**Fifty Years in Suffern.**—Dr. A. S. Zabriskie, on March 5, completed his fiftieth year as a practicing physician in Suffern. Dr. Zabriskie is 82 years old.

**The John Hodge Memorial Hospital.** erected in Lockport by the widow at a cost of \$10,000, has been formally turned over to the Home of the Friendless Association.

**The District Nurses** of Buffalo have received authority from the Health Commissioners and Common Council to act gratuitously as sanitary inspectors. As they visit the poorer districts much good is expected to be derived from their observations.

**The annual meeting** of the Erie County Medical Association was held March 10. Dr. De Lancey Rochester, the retiring president, delivered an address, and Dr. Allen Jones read a paper on the "Differential Diagnosis Between Dilated Gall-Bladder and Floating Kidney."

**Investigations of Charges.**—Charges of high death rate in infants under 2 years of age were made against the St. Mary's Infant Asylum of Buffalo by Dr. Julius Pohlman. Mr. George Lewis, as legal representative of the sisters, having invited the Buffalo Academy of Medicine, the Charity Organization Society and the Department of Health to appoint an investigation committee, the Academy has accordingly appointed Dr. Henry R. Hopkins, president of the State Medical Society; Dr. Ernest Wende, Dr. William Warren Potter, president State Board of Medical Examiners, Dr. Thomas F. Dwyer and Dr. Francis E. Fronczak as such committee. The committee is to report its findings as soon as possible.

**State Hospital Managers Retained.**—Governor Odell indicated clearly by some appointments he made, March 6, his intention to retain in the service of the state as many as possible of the former managers of the state hospitals for the insane, who were legislated out of office by a recent act. The appointments were those of members of the boards of visitation for the Utica State Hospital, the Hudson River State Hospital and the Binghamton State Hospital. Five persons were appointed as members of a board of visitation for each one of the three hospitals named. Thus fifteen appointments were made, and only one of these new appointments was that of a person not hitherto a manager.

#### New York City.

**Private Smallpox Hospitals.**—Commissioner Lederle has already received two offers of \$50,000 toward building private smallpox hospitals.

**To Reduce Mortgage.**—The Medical Society of Kings County is making strenuous efforts to reduce the mortgage of \$33,000 on its new building. Contributions of \$3250 have already been received.

**Dr. Knapp a Septuagenarian.**—Dr. Herman Knapp will celebrate his 70th birthday, March 17, and in 1904 his fiftieth anniversary as a medical practitioner. He was professor of ophthalmology at Heidelberg from 1864 to 1868. Since 1868 he has practiced his profession in New York City.

**Success of Consumption Hospital.**—Pleased with the success of the new tuberculosis division of the Metropolitan Hospital, the Commissioner of the Department of Public Charities has asked the Board of Estimate and Apportionment for \$40,000, with which to equip four other buildings as pavilions for the reception of phthisis patients, and for \$48,000 annually to maintain them.

**Medical Societies Agree.**—Dr. E. Eliot Harris, chairman of the Committee on Legislation of the New York State Medical Association, denies that Senator McCabe's Compulsory Vaccination bill is a source of dissension among the local and state medical societies, and says that the amendment proposed by the State Commissioner of Health modifies the drastic measures of the original bill, which inflicts three severe penalties for non-conformance with its provisions, and all the medical societies favor the amendment.

#### OHIO.

**Ashtabula General Hospital** has been incorporated at Ashtabula, with a capital stock of \$10,000.

**To Rebuild Hospital.**—A bill is before the legislature to issue \$1,000,000 in bonds to be used for the purpose of rebuilding the Cincinnati Hospital.

**Personal.**—Dr. Arthur F. Shepherd, Toledo, formerly of the staff of the Toledo State Hospital, has been appointed superintendent of the Dayton State Hospital.—Dr. Oliver P. Coe, Cincinnati, has been appointed resident physician to the Cincinnati Hospital at a recent meeting of the Board of Trustees, vice Dr. Walter Greiss, resigned.

**Dr. Drake's Picture Presented.**—At the meeting of the Marion County Medical Society, March 4, Dr. Russell C. Bowditch, the only surviving member of the organization of the Society in 1850, presented the Society with a life-size crayon picture of Dr. Daniel Drake, a pioneer physician of Cincinnati, who died in 1852. Dr. Drake wrote a work on "The Diseases of the Ohio Valley in the Northwest Territory," and contributed other works and papers on the prevailing diseases of the Queen City at an early day, and was among the early physicians in the organization of the Ohio Medical College and the Ohio State Medical Society.

**Severe Requirements Reduce Classes.**—The strictness of the medical laws in the State of Ohio has caused so great a decrease in attendance that combinations of various colleges are freely discussed. It is asserted that the coming fall will see the amalgamation of the Cincinnati College of Medicine and Surgery with the Miami Medical College, also of Cincinnati; as well as the Cleveland College of Physicians and Surgeons, controlled by the Ohio Wesleyan University of Delaware, Ohio, with the Medical Department of the Western Reserve University. It is needless to state that such combinations would be productive of the greatest good, not only in increasing teaching facilities but in raising the standard of medical education in the West.

**The Osteopathy Bill.**—The Cincinnati Academy of Medicine at its regular meeting of Feb. 3, 1902, took the following action:

The Academy of Medicine of Cincinnati urge most strongly upon the members of the Senate and General Assembly from Hamilton County to use their influence to defeat the osteopathic bill recently introduced and known as House Bill No. 170. This bill seeks to create a separate state board for the examination of those who desire to practice osteopathy, and has gone to the Judiciary Committee after two readings.

All physicians, no matter what school of medicine they desire to practice, must now secure their license from the Ohio State Board of Medical Examination and Registration. The law provides that those desiring to practice osteopathy shall only be examined on anatomy, physiology, chemistry and physical diagnosis—a list of subjects much less extensive than that in the bill presented. Osteopathy, according to its advocates, is based upon a knowledge of normal anatomy and the phenomena of disease, and they only claim special methods of cure. The present osteopathic bill, while it demands certain conditions and a period of study covering four courses of five months each, authorizes the osteopathic board to be created to dispense with these in their judgment, thus leaving them entirely free to act as they choose. The state is likely, therefore, to suffer an influx of ignorant and unqualified men, who will be free to treat disease of all kinds, for, in spite of their pretensions, we know that the osteopaths accept for treatment such diseases as cancer of the breast, goiter, eczema and rheumatism. We would call the attention of the delegation to the recent decision of the Supreme Court, State of Ohio vs. Gravett, in which osteopathy is defined as being the practice of medicine, and therefore coming under the supervision of the present law, the clause applying to them being only declared void because it specified four years' study being required before examination, while this period was not specified in that portion applying to other practitioners. In fact, the present state board required at that time that all colleges to be considered "in good standing" must have a full four-year course, and this was as equally binding as if specified in the law itself. The simple elision of the four-year clause will give the osteopaths full rights under the law to practice in Ohio provided they can pass the limited examination required of them. The creation of a separate examining board would, we feel, be a gross outrage upon the physicians of the state. [Signed] N. P. Dandridge, president; S. E. Cone, secretary.

#### PENNSYLVANIA.

##### Philadelphia.

**Refuses to Endorse Municipal Hospital.**—By a decisive vote the Philadelphia County Medical Society has refused to endorse the administration of the Municipal Hospital during the present epidemic of smallpox.

**Typhoid fever** is somewhat prevalent in the city, 107 new cases having been reported during the last week. There is considerable fear of an epidemic owing to the filthy condition of the water due to recent freshets.

**Expectoration in Public Places.**—The Woman's Sanitary League of Pennsylvania, at a recent session appointed a committee of the members to wait on the secretary of the State Board of Health with the idea of securing state action on the matter.

**Spring Medical School.**—The medical department of the University of Pennsylvania proposes to establish a spring school of medicine for post-graduates. Courses will be provided in nearly all branches, including chemistry, anatomy,

physiology, bacteriology and pathology. It is said that the medical faculty will take a prominent part in the instruction.

**Immunity.**—The James C. Wilson Medical Society and many of its friends were addressed on March 7, by Dr. William H. Welch of Johns Hopkins University, Baltimore. The address upon "Immunity" was marked by simplicity and clearness. The speaker avowed great faith in the Pasteur methods employed in combating rabies and anthrax, and believes there is practical value in the active immunity used against the plague. Serum therapy in its present state, he believes, is practically valuable in only three conditions, namely, tetanus, diphtheria and snake-bite. A reception was afterwards held at the University Club in honor of Dr. Welch.

#### TENNESSEE.

**Dr. John L. D. Walker**, Chattanooga, has been convicted of infanticide and sentenced to imprisonment in the penitentiary for ten years. He has been released on bonds pending a new trial.

**Sanatorium on Lookout Mountain.**—Dr. Howard J. Reynolds, Nashville, is about to locate a large sanatorium for the treatment of tuberculosis, on Lookout Mountain or Missionary Ridge, Chattanooga.

**Meharry Medical College Commencement.**—The medical department of Walden University, Nashville, held its twenty-sixth annual graduating exercises, February 26. The graduating class numbered 56.

**The Memphis controversy** has been settled by the Medical Society of the State of Tennessee, which has notified the original organization now known as the "Memphis and Shelby County Medical Society," that it would be recognized by the State Society as the county organization.

**St. Thomas' Hospital**, Nashville, was formally opened January 29. More than \$200,000 has been expended on its erection and equipment. The new part of the hospital contains 100 rooms, which are being furnished by Societies and individuals. The hospital is conducted by the Sisters of Mercy.

#### WISCONSIN.

**People's Hospital, Milwaukee.**—The new non-sectarian hospital to be erected on a site already selected by Rabbi Caro, is to be the People's Hospital. This is according to a suggestion made by Abraham Slimmer, who has offered to give \$25,000 toward the building of the institution. Mr. Slimmer greatly desires that Milwaukee shall take a hand in the building of the institution. It is estimated that a new building and site will cost from \$75,000 to \$100,000.

**Milwaukee Medical College Changes.**—The capital stock of the college has been increased from \$100,000 to \$150,000 and extensive improvements are contemplated, including an addition to the hospital. Dr. Joseph H. Wallis succeeds Dr. Henry F. Kortebein as lecturer on surgery; Dr. William Becker succeeds to the chair of nervous and mental diseases resigned by Dr. William F. Wegge, and Dr. H. V. Wuerdemann will take entire charge of the eye and ear department.

**Personal.**—Dr. Harry Greenberg, Milwaukee, who recently returned from Europe, has been made a contract surgeon in the army and ordered to Manila.—Dr. William F. Wegge, professor of nervous and mental diseases, and Dr. Henry F. Kortebein, instructor in surgery at the Milwaukee Medical College, have resigned.—Dr. Fred C. Kovats, Milwaukee, has been selected as interne at the Emergency Hospital.—Dr. B. L. Stinson, Milwaukee, has located at Hale's Corners.—Dr. George Smieding, Jefferson, has moved to Racine.—Dr. J. Willis Rockwell, Melrose, has located in Lancaster.—Dr. Donald J. O'Connor, physician of the state reformatory at Green Bay, has resigned and Dr. J. Percy S. Lenfestey, Depere, has been appointed to fill the vacancy; Dr. O'Connor has located in Escanaba, Mich.—Dr. Leo Breitzmann, Neenah, has located in Marinette.—Dr. C. I. Ide, who has been in charge of the Emergency Hospital, Milwaukee, for several months, will leave for Los Angeles, March 1.—Dr. Charles Ramally, North Bend, has moved to Melrose.—Dr. Joseph E. Harris, Reedsburg, who has just returned from a year's study in Vienna, will locate in Seattle, Wash.

#### GENERAL.

**Enno Sander Prize.**—The time limit for submitting the essays on "The Most Practicable Organization for the United States Army in Active Service," in competition for the Enno Sander prize, has been extended to March 31, 1902.

**Contract Surgeons Entitled to Salute.**—Contract surgeons in the Philippines are now entitled to receive a salute,

according to a recent circular issued by Gen. Chaffee, as the status of contract surgeons, contract dental surgeons and veterinarians of the artillery and cavalry, is assimilated to that of commissioned officers, they are entitled to the salute prescribed for commissioned officers in the Army Regulations.

#### Smallpox.

**Ontario:** Dr. Hodgetts, the provincial medical officer stationed at Sudbury, reports several cases of smallpox that have recently arrived at that place from the lumber camps. He says the mild weather is having the effect of making the camps break up early. The danger, Dr. Hodgetts says, of the disease spreading during the next month, should be observed by the local boards of health. He recommends that all the local boards keep under surveillance all men returning from the lumber camps. The smallpox report for the month of February shows that 707 cases were reported, with one death.

**Quebec:** The Quebec Board of Health has just been invested by order in Council with full powers in regard to sanitary regulations for camps, mines, etc. The board, acting on the order, has divided the province into ten districts, with an inspector for each. The powers thus granted by the board had been sought for some time without success, but the increased spread of smallpox seems to have stirred the government to action.

**Chicago:** Not one of the 16 new cases of smallpox discovered last week had ever been vaccinated. All but two of these were colored people—thirteen of whom were taken from one lodging house. From the nature of their occupations—waiters in hotels, restaurants and barber shops, porters, attendants on bowling alleys and other avocations bringing them into personal contact with numbers of people—the exposure has been unusually widespread.

**Buffalo:** More cases of smallpox have been reported in a hitherto unaffected portion of the city, but the health authorities have traced the source from the Polish district where the majority of cases have occurred.

**Philadelphia:** The number of smallpox cases continues to decrease each week; the new cases reported for the week ended March 8 are 47.

**Wisconsin:** At a special meeting of the Manitowoc Board of Health it was decided that the city would provide free vaccination to all those desiring it, and special efforts would be made to have all vaccinated. The city is to pay 25 cents each, and furnish the vaccine. It is estimated that this will cost the city over \$2000.

**Indiana:** A smallpox epidemic prevails in the southwestern part of the state which is known as the "pocket" of Indiana. There are 17 cases at Rockport, 15 at Birdseye and a number of cases of the disease at Evansville, Princeton and other towns. The disease prevails in an extremely mild form, however.

**Arkansas:** Smallpox is said to be raging throughout Mississippi County. Up to February 18, over 100 deaths had occurred; none of the victims had a vaccination scar, so far as could be learned by the local physicians. A proclamation was issued March 4, by the governor declaring smallpox epidemic in Perry County and naming the following board, upon the recommendation of President G. M. D. Cantrell of the State Board of Health: T. E. Holmes, J. P. McKinnis, J. N. Harris, Dr. J. W. Ryan, Jr., Dr. J. M. Mathews.

**Kansas:** During February 421 cases of smallpox in the state with no deaths were reported. The number of cases reported is much smaller than during the same period of last year in which 1335 cases occurred with 10 deaths.

**Michigan:** Smallpox was reported as being present in 153 places in the state during the last week.

**Nebraska:** At the meeting of the State Board of Health March 6, a report showing the number of cases of smallpox in the state during the month was made out. In the counties reporting, 764 cases are found, 189 of which are in Douglas County.

**Tennessee:** The secretary of the State Board of Health states that the smallpox situation in Tennessee is the best of any of the Southern States. It has been a hard fight for four years and now that the disease is becoming general all over the country this work is beginning to tell locally. There is far less of the disease than there was a year ago and there is nothing in the Tennessee situation to cause any alarm. The safe condition is due to the fact that the people of the state are well vaccinated. Between 60 and 75 per cent. of the entire population of the state has thus been made immune.

**District of Columbia:** Five new cases of smallpox developed during last week.

## CANADA.

**Grosse Isle Quarantine Station.**—New buildings have recently been erected at the above quarantine station at a cost of \$60,000.

**General Protestant Hospital, Ottawa.**—The 51st annual report of this institution has just been put in circulation. The total number of patients under treatment last year was 1400. Of these 702 were pay patients. In the outdoor departments 2163 patients were attended to.

**Obituaries.**—The death of Dr. James McLaren took place at his residence, Deer Park, North Toronto, on the morning of March 7. Deceased was born in 1824. He was graduated in Arts from Queen's College, Kingston, about 1850. He continued his college life in the medical faculty under Dr. Rolph, in the old Toronto School of Medicine, receiving his M.B. degree in 1853.—Dr. George W. Jackes, of Eglington, another suburb to the north of Toronto, died on the morning of March 7, of apoplexy. Deceased was in his 51st year, and had practiced in the same village for over twenty-five years.

**Vaccination Debated in the Quebec Legislature.**—A bill is before the Quebec legislature to amend the health laws of the province by curtailing the powers of the Provincial Board of Health in county municipalities and permitting municipal councils to take control of health matters. The promoter of the bill complains of the manner in which vaccination was controlled by the Board of Health, which he considers altogether too arbitrary. In face of the fact that smallpox is threatening to become generally epidemic throughout the province this legislator wishes to tie the hands of the Board of Health. The bill was referred to the Committee on Legislation, where Quebec people may well pray it may be lost.

**Congress of French Physicians of America.**—A very largely representative gathering of French-Canadian medical men was held the other evening at Laval University, Montreal, at which it was unanimously agreed to hold a congress of the French physicians of America, at the city of Quebec, during the month of June, the occasion being the celebration of the golden jubilee of Laval University of Quebec. Dr. Brochu, of Quebec, was elected president, and three vice-presidents were appointed: Dr. E. P. Lachapelle, to represent the city of Montreal and province of Quebec; Dr. C. Provost, to represent the province of Ontario; Dr. Archambault, of Cohoes, N. Y., to represent the United States. Two general secretaries were appointed: Dr. A. Simard of Quebec, and Dr. Lesage of Montreal.

**Medical Matriculation by Act of Parliament.**—A discussion took place one afternoon last week in the Quebec legislature upon a bill introduced by a member thereof to permit medical students who commenced study prior to 1899 and who omitted to pass their preliminary examination to dispense with it. It appears that in 1898 a similar measure was passed for the benefit of those who had commenced their studies prior to 1896. This established a precedent for other students lacking a classical education to run the same risk, thinking that the legislature would see them through. The Hon. Mr. Flynn, leader of the opposition, ridiculed the measure, stating that if this sort of thing were to continue, classical education for entrance to the professions had better be abolished. Hon. Dr. Guerin moved the six months' hoist, which was adopted by a vote of 45 to 15.

**Toronto Clinical Society.**—At the regular meeting of the Toronto Clinical Society Dr. Herbert A. Bruce reported a case of typhoid fever with perforation, operation followed by recovery, with a subsequent subphrenic abscess, operation and recovery. This is the first successful case reported in Canada of perforation in typhoid fever operated on with recovery. The patient was a young medical practitioner, aged 28, practicing in a western Ontario town. Whilst in the performance of his duties last summer he contracted typhoid fever. The case went on in the usual way until along in the third week the patient was seized in the middle of one night with excruciating pains in the right iliac fossa. His physician was summoned but being absent in the country a fellow practitioner was despatched in his place. The pains were quieted with a hypodermic of morphia and on the following day his regular attendant arrived and diagnosed a perforation of the bowel. For this diagnosis he held out against three other practitioners and Dr. Bruce was summoned from Toronto. The diagnosis of perforation was confirmed by Dr. Bruce and an operation at once undertaken. This was some eighteen hours after the perforation was supposed to have occurred. The patient recovered nicely, until some time after Dr. Bruce was again summoned to his bedside and then a diagnosis was made of subphrenic abscess. This was operated on and two and a half

quarts of pus were evacuated. The patient very nearly collapsed after this operation, but finally rallied and was present at the meeting of the Clinical Society along with his attending confrère.

## FOREIGN.

**Egyptian Medical Congress.**—The 1st Egyptian Medical Congress will be held December 19 to 23, 1903, instead of December 10 to 14.

**Death of Julius Wolff.**—Professor and privy councillor Wolff owes his renown to his achievements in surgery and orthopedics. He was appointed director of the orthopedic surgical clinic at Berlin in 1884, and was in his 67th year at the time of his death, February 17.

**Skoda's Pupils.**—The Vienna University is preparing a memorial Festschrift in honor of the centennial celebration of the birthday of Josef Skoda. The committee in charge appeal to all who were at any time students under him to look up all their note books, etc., with records of the master. The committee beg for the loan of all such material, guaranteeing its safe return. The appeal is signed by Nothmager, Schrötter, Benedikt, von Töply and Neuburger.

## State Boards of Registration.

**Washington State Examination.**—The State Board of Medical Examiners held its semi-annual examination at Tacoma on January 7 and 8. The standard requirements for those having practiced ten years or over is a general average of 70 per cent.; those having practiced less than ten years are required to obtain an average of 75 per cent. The number of candidates was 60, of whom 42 were successful.

## Decapsulation of Kidney for Chronic Bright's Disease.

HOT SPRINGS, ARK., March 4, 1902.

To the Editor:—Since reading the admirable article of Dr. Geo. H. Edebohlts, on decapsulation of the kidneys for chronic Bright's disease (*Medical Record*, Dec. 21, 1901, and *THE JOURNAL*, Jan. 4, 1902, p. 62), I am impressed with its far-reaching possibilities. It opens up a vast field of work in the cure of otherwise hopeless cases. Why could not this same procedure be resorted to in cirrhosis of the liver before the stage of atrophy sets in? Decapsulation of the upper surface of this organ would certainly take away a very great obstacle to the speedy formation of many large blood vessels for anastomotic duty. True, we have this anastomosis in a certain degree when we remove the epithelium by means of our friction with gauze sponges; but it is easy to see the vast difference between the small vessels which would penetrate this capsule and the very free circulation which would ensue if this membrane is partially removed.

Hence I would urge: 1, that the operation of Talma for acites be performed while the liver is large and swollen with inflammatory products, and before the period of organization and consequent contraction, the stage of atrophy, sets in; and 2, that in addition to the omental and abdominal wall anastomosis that the capsule of the superior surface of the liver be resected, instead of being simply rubbed with gauze.

This could very easily be carried out by making an additional incision along the edge of the ribs when the surface of the liver could be easily reached. Such additional incision will not materially augment the dangers of the operation, and we quickly provide means whereby the inflammatory material may be absorbed and removed. Yours truly,

JAMES T. JELKS, M.D.

## Membership in County and National Societies.

SAN DIEGO, CAL., Feb. 28, 1902.

To the Editor:—In *THE JOURNAL* of February 22, page 525, is a communication suggesting to the effect that a clause in the by-laws affecting membership in the Association be so drawn as to except from its operation those members who for any reason have not maintained membership in the county society and do not desire to re-enter it. It seems to me that such a clause would be objectionable, distinctly retrograde and impolitic. It is one of the avowed objects, in fact the chief object, of the re-organization to effect a more thorough and perfect organization of the profession generally, and the county society is, by the proposed scheme of reorganization, to be the unit. I submit that it would be, to say the least, impolitic to create a class who might remain members of the Association and yet not be members of the local society; it would be a bad precedent. It should be no hardship for any member of the Association to become a member of his county society; indeed, I deem it his duty to the profession generally, and to himself especially, to be an active member of his county society, which will, by the way, be just what the local profession make it.

A physician in practice, if he is young and inexperienced, should be an active member that he may learn and benefit by such membership; if he is learned and experienced it is his duty to attend and instruct those who are or have been less favored than he; indeed, they ought to have the right to require such service at his hands. If it be required of a new member of the Association that he be a member and maintain membership and standing in his county society, surely an old member ought not to object to the application of the rule himself, "equal rights to all, special privilege to none." While it may not be germane to the subject at this time, I wish to state that it is my belief that no more effective way of raising the standard of ethical practice can be devised than that a rule should prevail that no license to practice should be issued except that the applicant be a member of the county society and in good standing, and that he should, in order to retain his license, retain his membership and standing.

WILLIAM M. CUMMINGS, M.D.

## Deaths and Obituaries.

## Christian Fenger.

Christian Fenger was born, Nov. 3, 1840, in Copenhagen, Denmark. Following in the footsteps of his uncle, Professor Emil Fenger, he decided to study medicine. While still a student, war broke out between Denmark and Germany, and he served as surgeon throughout that campaign. In 1867 he received his diploma. For two years he was assistant to Wilhelm Mayer in his ear clinic, and during 1868 and 1869, an interne in the Friedrich's Hospital, Copenhagen. When war was declared between France and Germany Dr. Fenger became surgeon in the Red Cross ambulance corps and served in that capacity during the war with the French army. He then studied in Vienna under Professor Billroth, returned in the winter of 1871 to Denmark and was prosecutor at the Copenhagen City Hospital from 1871 to 1874. In 1874 he presented and defended a thesis on "Carcinoma of the Stomach; Its Anatomy, Development and Extension," which gained for him the position of lecturer at the university. Late in 1874 he was made extraordinary professor of pathological anatomy. In 1875 he went to Egypt, was made a member of the Conseil Militaire and surgeon-in-charge of the Khalifa quarter of Cairo. Two years later he came to America and settled in Chicago. In 1878 he was appointed to the attending staff of Cook County Hospital, and in 1880 was made curator of the Rush Medical College museum. In 1887 he was elected professor of clinical surgery at the College of Physicians and Surgeons; nine years later he was made professor of clinical surgery at the Chicago Medical College, and in 1899 he was appointed to the same chair in Rush Medical College. During the last twenty-five years he has been surgeon to Cook County, Presbyterian, Mercy, Tabitha Norwegian, Passavant Memorial, Lutheran, German, and German-American Hospitals.

He died at 9:45 p. m., March 7, 1902, at his home in Chicago, after an illness of one week. The cause of his death was croupous pneumonia. True to his principles that he had so often taught, he requested, when he knew that he might die, that a postmortem examination be made. This request was complied with. In addition to the pneumonia, which involved the upper and middle lobes of the right lung, there were found an obliterating, healed tubercular pleuritis with calcareous bronchial glands, and three gallstones in the gall-bladder. A few months before his death, Dr. Fenger had had a slight attack of what he himself recognized as gallstone colic.

The funeral services were held at the New England Congregational Church, of which Dr. Fenger had for ten years been a member, the pastor, Rev. W. Douglas Mackenzie officiating. The interment was at Rosehill Cemetery.

The active pall-bearers, selected from Dr. Fenger's personal assistants, were Drs. Ludvig Hektoen, William E. Morgan, Samuel C. Stanton, James B. Herrick, M. L. Harris, A. Holmboe, C. Doepfner and Andreas Frick. The honorary pall-bearers, representing the University of Chicago, the medical colleges, medical societies and hospitals, were as follows: University of Chicago, President William R. Harper; Rush Medical College, affiliated with the University of Chicago, Drs. N. Senn and Frank Billings; Northwestern University Medical School, Dr. N. S. Davis, Jr.; College of Physicians and Surgeons, Dr. William E. Quine; Chicago Policlinic, Dr. Fernand Henrotin; Chicago Medical Society, Dr. N. S. Davis, Sr.; German Medical Society, Dr. Gustav Fütterer; Scandinavian Medical Society, Dr. N. Johnsen; Chicago Gynecological Society, Dr. Lester Frankenthal; Chicago Surgical Society, Dr. John B. Murphy; Chicago Pathological Society, Dr. Frank B. Earle; Medicolegal Society, Dr. W. L. Bunn; Chicago Academy of Medicine, Dr. Harold N. Moyer; Journal of the American Medical Association, Dr. E. Fletcher Ingals; Presbyterian Hospital, Dr. Arthur D. Bevan; Passavant Memorial Hospital, Dr. H. B. Favill; Evanston Hospital, Dr. John Ridlon; German Hospital, Dr. J. H. Hoelscher; German-American Hospital, Dr. John Fisher; Tabitha Norwegian Hospital, Dr. B. Meyer; Cook County Hospital, Dr. Arthur R. Edwards and Dr. Frank S. Johnson.

Christian Fenger was generally recognized as one of the greatest surgeons of America, and his reputation was international. His contributions to medical literature were numerous, more than eighty articles being credited to him. When one remembers that he had made thousands of autopsies in Europe and in Chicago, that he was an expert microscopist, having had training in Arnold's laboratory, that he made it a practice to examine histologically and bacteriologically the specimens he obtained at his operations or at autopsies on his patients who

died, one understands why these articles are always based upon a sound and scientific pathological foundation, and are not solely the so-called "practical" articles. Experimental work upon the lower animals and the cadaver was frequently employed to prove his points. At the time of his death he was engaged in experimental work upon the kidney, in a knowledge of the surgical affections of which organ he has been declared, by a competent judge, to stand next to Simon and James Israel. These contributions were valuable also because he kept careful records of the cases used as the basis of his articles and because he made an exhaustive study of all similar recorded cases and of all literature bearing upon the subject in hand. His style was clear, shorn of unnecessary verbiage and characterized by an orderliness and system that were sometimes a surprise to those who heard him speak or read, and found it difficult to understand his somewhat hesitating and not fluent speech. But after all, the chief value of these contributions consists in the fact that this knowledge, pathological, clinical and bibliographical, was all carefully worked over and analyzed by that wonderfully logical mind, so that his reasoning seemed faultless and his conclusions inevitable. So careful was he in his observations, so impartially judicial in his decisions that one hesitated long before disputing any conclusions he had reached. That there was aught but absolute honesty in his work was never hinted at, even in the whispered and gossiping confidences of idle talk.

His work as a writer is solid, and will stand the closest criticism. Much of it is for all time. There is nothing that he has written, at least nothing with which we are familiar, that does not contain something of value, valuable at least for the time at which it was produced; some common error is corrected, some old truth presented in a new light, or some new discovery given to the medical world. Among the more important of his writings may be mentioned: "Nerve-stretching"; "Total extirpation of the uterus through the vagina"; "Hyperplastic salpingitis"; "Operation for the relief of valve formation and stricture of the ureter in hydro- or pyo-nephrosis"; "Basal hernias of the brain"; "Conservative treatment of sacculated kidneys; cysto-nephrosis"; "Stones in the common duct and their surgical treatment; with remarks on the ball-valve action of floating choledochus stones"; "Diseases of the ureter."

As a speaker he lacked fluency. His hesitating speech made it at first difficult to follow him. Yet he never lacked an audience at clinic, ward operation or at discussion in a medical society. And it is true that, to a certain extent, one could judge of the caliber of a man by finding out that man's estimate of Dr. Fenger as a speaker or clinical teacher. The best men listened respectfully as to a master; the poor or mediocre man became impatient, criticised, and was happy in his ignorance.

As an operator Dr. Fenger was painstaking and thorough.

He was never a rapid workman. His operations on tubercular glands of the neck or carcinoma of the breast were lessons in thoroughness that often made other surgeons who flattered themselves that they had been careful in the removal of all diseased tissues, blush with shame as they thought of their own comparatively hasty and careless work. He thoughtfully considered every step of the operation. He always knew exactly where he was and with what anatomic structure he was dealing. He left nothing to chance. If in doubt as to the nature of a growth he stopped in his operation and examined microscopically; he often had books and drawings at his side during an operation to be consulted if need be; he ligated vessels that other surgeons would have let alone, trusting they would not bleed; he drained where others did not; he was almost finical about asepsis. This attention to the minutiae, this extraor-

inary carefulness and thoroughness were well known to physicians and to patients, and gave the laity and the profession unusual confidence in him as a man who could be trusted to do the right thing and only the right thing on the operating table. And this same thoroughness explained his wonderfully successful results. He was a fearless operator but absolutely without a taint of recklessness. No surgical procedure was too formidable to be undertaken if justifiable. But no love of applause, no large fee, no morbid curiosity to see what could be done, tempted him to subject a human being to a procedure that he regarded as unjustifiable. He was a most conservative surgeon, erring oftener perhaps on the side of conservatism than of radicalism. One of his latest works is against the indiscriminate treatment of peritoneal tuberculosis by surgical measures.

His wonderful knowledge of pathology and morbid anatomy, his extreme caution in forming his opinion until all known means of information had been exhausted and his philosophical and logical modes of thinking made his advice in matters of diagnosis in great demand, and his decision was generally regarded as final and his judgment generally found to be correct. Yet he was most ready to acknowledge his

limitations and often confessed his ignorance. "God only knows, and He will not tell," he often said when a case baffled all diagnostic or prognostic skill. He had the courage to acknowledge his mistakes of judgment or of technique as only a great man is capable of doing.

To the medical world in general the death of Christian Fenger means the loss of one of its great surgeons. To those who have lived in Chicago and the Northwest and have come within the circle of his immediate influence the loss is keenly felt as a personal one, and the place that he leaves vacant can never be filled by another. The death of no physician in the Northwest will be so sincerely mourned by so many physicians as that of Dr. Fenger.

But what was the mysterious charm by which he drew all

*Christian Fenger*

toward him? What was there in this quiet, modest, plain man, of simple tastes, of faltering speech that attracted all who came near him? It is always difficult to analyze a man's character and tabulate his qualities. The personal element really defies analysis. But it would seem as though the trait of character that made Dr. Fenger strong was his impersonation of truth. He was its very embodiment. His looks spoke of sterling integrity, his manner was unassuming, yet one of earnestness and sincerity. Whether one watched his careful, painstaking operation; whether one listened to his lectures or discussions where he slowly, but with irresistible logic made his meaning plain; whether one read his articles, clearly written, systematic and thorough, or whether one watched him step by step unraveling the intricacies of a perplexing case; wherever and whenever one saw or heard him there was the same impression created that here was a man who was aiming to seek out truth for truth's sake, and this is the essence of science. Fenger was the incarnation of the scientific spirit in surgery. Men about him saw this, they felt it; he imparted this spirit to them. Herein lay one of the elements that made him strong and a man of influence. Coming to Chicago as he did, twenty-five years ago, at a time when the new light of modern pathology had not yet broken upon the Northwest, he began his mission of imparting the truths of this recreated science. Against much opposition, in spite of many drawbacks, he fought his way. Others began to see the light that he had seen and were eager to learn of him. To hospital internes, to medical students, to doctors, to any one who showed a desire to learn and a willingness to study, he was glad to talk of things surgical and pathological. He sacrificed leisure and pleasure that he might help them.

The value of this work is incalculable, and only appreciated by those who know the conditions existing twenty-five years ago and the difficulties he encountered in his endeavors to spread the new knowledge. This is really Fenger's great work. He is revered as the father of scientific surgery in the Northwest, and with Senn in experimental work aroused this section of the country so that now there has grown up a group of well-known younger men who freely acknowledge that the right impetus to study was given them by this remarkable man. When the intellectual history of Chicago comes to be written, high among the great names will be that of Christian Fenger.

The casual observer sometimes thought him rough in his manner, unsympathetic, one who delighted in the use of the knife and whose finer sensibilities had been blunted. But nothing could be farther from the truth. He was as pure-hearted as a child, even child-like in his simplicity in many respects. He had the finest of fiber in his make-up. He loved flowers, beautiful scenery and children, and was not ashamed to show it. He was an unusually fine art critic and a lover of fine pictures. He himself had an ability to sketch with crayon or pencil that was of great help to him as a teacher. He was a linguist with a working knowledge of some seven or eight languages; he was a man of culture and refinement; he was incapable of a mean act; he had the soul of honor; he was a gentleman in the truest sense of the word. He was lovable and loving to a degree seldom granted to man. It is not meet to refer here to his domestic relations. But the grief-stricken wife and the two children who survive him know, as no one else can know, the depths of that great, true heart, and will always cherish the memory of a love and devotion such as are rarely seen.

It is a cause for congratulation that Dr. Fenger's friends and admirers let him and the world know of the esteem and love in which he was held. His colleagues among the Scandinavian colony in Chicago looked up to him as their honored leader, were proud of him and at every meeting of their medical society, whether he were present or not, drank the health of Christian Fenger. At the time of his death he was the president of the Chicago Medical Society, and for the second time of the Chicago Surgical Society. On Nov. 3, 1900, the medical profession of the country gave him a dinner, the occasion being the sixtieth anniversary of his birth. Over 500 physicians attended. This honor was deeply appreciated by Dr. Fenger. But no testimonial, no office of honor, was a more eloquent tribute to this man's character than the gathering at the funeral services. It is doubtful if so great a number of physicians have ever before come together in Chicago for such a purpose. The sad faces of his colleagues, and the tear-dimmed eyes of the long line of men and women, many of them his old patients and evidently from the poorer walks of life, as they took a last look at this beloved physician, spoke more than any uttered word.

It seemed as though he had several years of usefulness and happiness before him. But perhaps it is best that he should be

cut down in the midst of his active work, with his mind still strong and vigorous, his eye undimmed, his hand steady, rather than that ruthless old age should rob him of any of those attributes with which we link his name. His work was in reality done. His monument is already erected in his medical writings, in the group of men whom he influenced and aroused to a higher scientific life, in the elevation of medical thought in the Northwest, in the example of an untiring devotion to truth, in the love that is left in the hearts of all who knew him.

#### Dr. Edward Mott Moore.

Dr. Moore graduated from the University of Pennsylvania in 1838. After a service as interne in Philadelphia, he went to Rochester, N. Y., and practiced there, filling the chair of surgery at Vermont Medical College, Woodstock, from 1842 to 1854, and thereafter at Berkshire Medical College, Pittsfield, Mass., and Starling Medical College, Columbus, Ohio. From 1858 to 1883 he was professor of surgery at Buffalo Medical College. He was a member of the American Medical Association, and its president in 1890; one of the founders of the New York State Medical Society, and its president in 1874; one of the founders of the American Surgical Association, over which he presided for one term, and president of the State Board of

EDWARD MOTT MOORE.

Health from its organization until 1855. He was a delegate to the International Medical Congress at Copenhagen in 1894, and for many years was president of the board of trustees of the University of Rochester. He died March 3 at his home in Rochester, from bronchitis, aged 88. Various medical and lay organizations of Rochester met and took action on Dr. Moore's death. The Rochester Academy of Medicine, at a meeting held March 5, took the following action:

We have heard with deep regret of the death, on March 3, 1902, of Edward Mott Moore, M.D., LL.D., the first Honorary Fellow of this Academy. It seems but a short time since Dr. Moore's acceptance of his election as Honorary Fellow was read to us. This was probably the last scientific organization which he honored by his membership. Many present will remember the occasion upon which he addressed the Academy upon the subject of "Fractures of the Clavicle," and will recall with pleasure his urbanity and grace, and the clearness which marked his statements. His mind seemed undimmed, and we hoped that he might be spared for many years to the city and to the profession which he loved so well. His death removes the oldest and ablest physician identified with the history of Rochester. Those of us have been fortunate who have been honored with his acquaintance and have come under his influence. Dr. Moore's life has been an inspiring illustration of high conceptions of the science of medicine and the humanities of life which should ever attach to its practice.

It was further Resolved, That the foregoing memorial be engrossed on the minutes of the Academy; that a copy thereof be

sent to the family of the deceased; and that such action be transmitted to The Journal of the American Medical Association. [Signed] J. W. Whitbeck, William S. Ely, Edward W. Mulligan, T. A. O'Hare, G. W. Goler, Committee.

The Monroe County Medical Society, at a special meeting held March 4, adopted the following minute:

Dr. Edward Mott Moore, for many years a member of this Society and once its president, died in this city March 3, 1902, in his 88th year. For seventy-two years Dr. Moore had been a resident of Rochester. After an excellent preliminary education, general and technical, he studied medicine and graduated at the University of Pennsylvania in 1838. In 1841 he began his work as lecturer, which was carried on for many years in medical colleges in Woodstock, Vt.; Pittsfield, Mass.; Cleveland and Buffalo.

During this time he was actively engaged in the study and practice of his profession. As a surgeon he was widely known and had a vast experience. His career embraced many of the wonderful achievements in medical science with which we are all familiar.

He performed major operations before the introduction of anesthesia in 1846. He was hospitable to new ideas, kept in touch with all real progress in his profession, and was closely associated with important discoveries and improved methods. He was the head of the staff of St. Mary's Hospital in this city from the founding of that institution.

Dr. Moore was a man of strong intellectual gifts—a clear vision, sane judgment, equitable temper, absolute self-control. He loved the society of the young, sympathized with the bright and ambitious student and was generous with his advice and help. His mind was essentially scientific and practical, therefore it followed necessarily that he was one of the first to accept the doctrines of Darwin and Spencer, and to interest himself in biological studies.

Dr. Moore was an advocate of independence in politics, of every civic reform. His influence for good in our city was constant, quiet, effective. His later years he devoted exclusively to the development of our system of park, working with wonderful prevision for the remote future and not merely the immediate present. That work gave him the distinction of being the father of the parks. His plans, if carried out, will more and more serve to keep alive his memory.

We have lost the oldest and the wisest of our medical friends. He had passed far beyond the four-score limit, yet only his physical strength had abated. He was still our trusted counselor and our staunch friend. We revered him only the more as time went on. We are grateful for the benefits that we enjoyed in this long and intimate relation of friendship, and shall continue under his influence, though he is withdrawn from our sight.

We adopt as our own expression the inscription of a memorial in St. Paul's cathedral, London, to an English physician: "Eminently distinguished for science. Beloved for the simplicity of his manners and the benevolence of his heart. Respected for his inflexible integrity. In all the relations of his professional life he was sagacious, cordial, diligent and humane."

We tender to his family, particularly to the sons who are our fellow members, our heartfelt appreciation and sympathy.

The Rochester Chamber of Commerce adopted the following minute:

The Rochester Chamber of Commerce records its high appreciation of the memory of Edward Mott Moore, who, modest in greatness, lived a long, useful and conspicuous life in Rochester.

He honored his city by eminent talents devoted to the alleviation of human suffering.

With far-seeing wisdom, he served his fellow citizens and future generations by securing to their use great gifts of nature within the municipal boundaries, and they are now his lasting monument.

**Francis W. Lewis, M.D.** Jefferson Medical College, Philadelphia, died from pneumonia, March 2, at his home in Philadelphia, aged 76. Ever since the founding of the Children's Hospital he has been identified with its interests, and was for many years president of its board. He was public spirited, serving upon the boards of the Academy of Fine Arts, the Library Company of Philadelphia, and the Zoological Society for many years. He was a member of the College of Physicians and other learned societies, and was also a member of leading social clubs.

**William S. Crawford, M.D.** Washington University, St. Louis, 1870, a leading practitioner and country physician of Jo. Daviess County, Ill., died from apoplexy at his home in Galena, February 28, after an illness of five days, aged 54. He was a native of Galena; a son of Dr. John S. Crawford, one of the early settlers of that city; studied in the Western Reserve University, Cleveland, and Rush Medical College, Chicago, finally graduating at St. Louis Medical College. He practiced with his father until the death of the latter.

**Edwin Sinnett, M.D.** Medical College of Ohio, 1850, was a life member of the Ohio State Medical Society, and army surgeon during the last two years of the Civil war. Though modest and retiring, he took an active part in Grand Army and in civic life. He served his town at some time in his career in all its offices, and his state in the upper house of the General Assembly through two terms. He died at his home in Granville, Ohio, February 22, in his 75th year.

**John C. Nicholson, M.D.** Jefferson Medical College, 1855, one of the oldest surgeons of Alabama, died at his home in Mount Meigs, March 3, aged 73, after a lingering illness. He was a member of Montgomery County and Alabama State Medical Societies and was prominent in agricultural organiza-

tions. He served through the Civil war, was once a member of the state legislature and rendered public service in many ways.

**Hugh L. Cheney, M.D.** Medical College of Ohio, Cincinnati, 1847, a pioneer resident and practitioner of Franklin County, Ohio, died at his residence in Columbus, February 26, aged 82. He had been prevented from the practice of his profession for about twenty years by ill health, and was totally blind for a long time.

**William C. Spearman, M.D.** Louisville (Ky.) Medical College, 1885, died of appendicitis at his home, Texarkana, Ark., February 21, aged 48. He was a member of the American Medical Association and the Arkansas Medical Society, and had been a member of the State Board of Health for 5 years.

**Benjamin F. Kitchen, M.D.** Medical College of Ohio, Cincinnati, 1871, formerly a representative in the state legislature from Jackson County, and at the time of his death the oldest practitioner in the county, died suddenly from heart disease at his home in Wellston, February 25, aged 67.

**Morris W. Townsend, M.D.** Jefferson Medical College, 1853, president of the Genesee County Medical Society, member of the New York State and American Medical Associations, died at his home in Bergen, N. Y., February 26, of cardiac hypertrophy, aged 75.

**David C. Galbraith, M.D.** Medical College of Ohio, Cincinnati, 1865, an old practitioner of Franklin, Pa., who served during the Civil war as surgeon under General Butler, died at Brunswick, Ga., where he had gone in the attempt to regain his health, February 28.

**Herkimer B. Miner, M.D.** College of Physicians and Surgeons of the Western District of New York, Fairfield, 1834, for more than fifty years a practitioner in West Mendon and Honeoye Falls, N. Y., died at his home in the latter place, March 2, aged 96.

**E. Newlin Williams, M.D.** University of Pennsylvania, 1898, died from cold and exposure, about February 8, in the White Mountains, near Glencliff, N. H., aged 28. His home was in Philadelphia, and he was on his way to inspect some wooded property.

**Henry Ayres Hyland, M.D.** Baltimore University, 1892, a well-known physician of Northeast Baltimore, and for a time demonstrator of anatomy at the University of Maryland, died at his home in Baltimore, February 26, from pneumonia, aged 47.

**Richard Ferguson, M.D.** University College of Medicine, Richmond, Va., 1897, formerly of Richmond, Va., was found dead in his house in Columbia, S. C., March 6. Death was due to chloroform, which it is supposed he inhaled to induce sleep.

**Ervin A. Tucker, M.D.** College of Physicians and Surgeons, New York, 1889, teacher of obstetrics and gynecology in Columbia University, attendant at Sloane Maternity Hospital, died at his home in New York City, March 3, of pneumonia.

**Joseph W. Winslow, M.D.** Berkshire Medical College, Pittsfield, Mass., 1845, for over fifty years a physician in Easthampton and Enfield, Mass., died, February 24, at his home in the latter place, aged 83, from a paralytic shock.

**Rudolph B. Menard, M.D.** Laval University, Quebec, 1897, a young physician of Biddeford, Me., was thrown from his carriage, February 15, and died at his apartments, February 20, without having regained consciousness, aged 29.

**William E. Bibb, M.D.** Jefferson Medical College, Philadelphia, 1848, a prominent physician of Albemarle County, Va., where he had practiced for fifty-four years, died at his residence near Free Union, February 28, aged 76.

**William B. Hanes, M.D.** Detroit (Mich.) College of Medicine, 1901, house physician at Harper Hospital, Detroit, died, March 3, from septicemia, contracted while performing an autopsy. He was 25 years of age.

**Albigeance W. Kingsley, M.D.** Castleton (Vt.) Medical College, a practicing dentist in Elizabeth, N. J., for nearly fifty years, died at his winter home in Maitland, Fla., March 3, from angina pectoris, aged 86.

**Sherman J. Hadley, M.D.** Omaha (Neb.) Medical College, 1888, who practiced in Arlington, Neb., but was obliged, on account of his health, to go to Hot Springs, S. Dak., died in that place, March 1, aged 66.

**Seth M. Benepe, M.D.** Bellevue Hospital Medical College, New York, 1866, died at his home in Sebastopol, Sonoma County, Cal., February 20, seventeen months after a cerebral hemorrhage, aged 54.

## Association News.

### Report of the Committee on Transportation.

WASHINGTON, D. C., March 8, 1902.

The Committee of the American Medical Association on Transportation, reports that the rates for railroad transportation to the Saratoga meeting are being arranged for in the various railroad associations, and special prominence has been given to the disapproval of the medical profession of the methods of the Western Association in exacting the annoying fifty-cent execution fee which was perpetrated upon the members attending the St. Paul meeting. Assurances have been given that this will not occur at the Saratoga meeting, and at this writing the Trunk Lines have offered a fare and a third on the certificate plan for the round trip. Your Committee is urging a one-fare rate for the round trip with a 30-day-extension time limit and the privilege of a diverse route returning. Dr. Swan, of the local railroad committee at Saratoga, N. Y., is taking an active interest in the matter of rates, and is coöperating with the Committee of the Association. The combined efforts of the Committees are directed towards securing a one-fare rate for the round trip. Progress in this direction will be announced from time to time in THE JOURNAL.

H. L. E. JOHNSON, Chairman.

## Societies.

### COMING MEETINGS.

Medical Association of the Missouri Valley, Lincoln, Neb., March 20, 1902.

American Association of Pathologists and Bacteriologists, Cleveland, O., March 28-29, 1902.

Medical Association of the District of Columbia, Washington, April 1, 1902.

Tri-State Medical Society of Iowa, Illinois and Missouri, Chicago, April 3-4, 1902.

Tennessee State Medical Society, Memphis, April 8, 1902.

Florida Medical Association, Tampa, April 9, 1902.

Western Ophthalmological and Oto-Laryngological Association, Chicago, April 10-12, 1902.

Medical Association of the State of Alabama, Birmingham, April 15, 1902.

Medical Society of the State of California, San Francisco, April 15-17, 1902.

Medical Association of Georgia, Savannah, April 16, 1902.

Mississippi State Medical Association, Jackson, April 16, 1902.

South Carolina Medical Association, Spartanburg, April 16-17, 1902.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.

Association of American Physicians, Washington, D. C., April 29-30, 1902.

American Association of Genito-Urinary Surgeons, Atlantic City, N. J., April 30, 1902.

**Delaware State Medical Society.**—This Society will change the date of its annual meeting so as not to conflict with that of the American Medical Association.

**Manchester (N. H.) Medical Association.**—The fifth annual banquet of the Association was held February 26. Dr. John M. Gile, Hanover, was the guest of honor and delivered an address on "Intestinal Obstruction."

**Alton (Ill.) Medical Society.**—This Society has elected the following officers: Dr. Titus P. Yerkes, Upper Alton, president; Dr. Frank Worden, North Alton, vice-president; Dr. George E. Wilkinson, Alton, secretary; Dr. Charles Davis, Alton, recording secretary, and Dr. Waldo Fisher, Alton, treasurer.

**Putnam County (Tenn.) Medical Society.**—At the meeting of this Society in Cookeville, March 3, the following officers were elected: Dr. Samuel Denton, Buffalo Valley, president; Drs. J. B. S. Martin and H. R. Ragland, Cookeville, vice-presidents; Dr. John T. Moore, Algood, secretary, and Dr. Claude P. Martin, Cookeville, treasurer.

**Cincinnati Academy of Medicine.**—At a meeting of the Academy, March 3, the following officers were elected for the ensuing year: Dr. Asa B. Isham, president; Drs. Brooks F. Beebe and Ellen F. McCarthy, vice-presidents; Dr. Stephen E. Cone, secretary; Dr. Arch I. Carson, librarian; Dr. Magnus A. Tate, treasurer; Drs. Byron A. Stanton, James F. Heady, and N. Pendleton Dandridge, trustees.

**Fred Lynn, M.D.** Western Reserve Medical College, Cleveland, a practitioner of Cortland, Ohio, who went to Mexico six months ago for his health, died there, February 22, from consumption, aged 25.

**William M. Madison, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1876, an old practitioner of Farmington, Mo., died from pneumonia at his home in that place, February 24, aged 55.

**William D. Kearns, M.D.** New York University, 1857, one of the best-known practitioners of Pittsburgh, where he had practiced for 44 years, died from pneumonia at his home, February 24, aged 71.

**Wellington Carleton, M.D.** Detroit (Mich.) Medical College, 1871, one of the best-known practitioners of Ogle County, Ill., died at his home in Rochelle, March 2, from pneumonia, aged 60.

**Theodore Turnbull, M.D.** University of Maryland School of Medicine, Baltimore, 1881, a physician of Monticello, Fla., died at Baltimore after an operation, February 24, aged 41.

**Francis H. Russell, M.D.** Bellevue Hospital Medical College, New York, 1871, died, February 24, of paralysis of the throat, aged 54, at his home in Farmington, Me.

**H. W. Sparks, M.D.** Louisville (Ky.) Medical College, 1890, of Denton and Ashland, Ky., died at the former place, February 26, of pneumonia, at about 38 years of age.

**William R. Neblett, M.D.** University of Nashville, Tenn., 1867, died, February 27, aged 66, at his home in Chattanooga, where he had retired because of ill health.

**Benjamin F. McCuiston, M.D.** Kentucky School of Medicine, Louisville, 1890, was shot and killed by A. W. McComas at Paris, Texas, February 28.

**Joseph A. Booth, M.D.** College of Physicians and Surgeons, New York, 1882, died from heart disease at his residence in New York City, February 26, aged 62.

**Conrad Mund, M.D.** College of Physicians and Surgeons, New York, was drowned while sailing in Great South Bay, March 2. He was 28 years old.

**Orrin M. Bailey, M.D.** Western Reserve University, 1874, an old practitioner of Greensburg, Ohio, died from cancer at Warren, Ohio, February 24.

**John K. Scribner, M.D.** Jefferson Medical College, 1894, formerly of Pittsburgh, died at Finleyville, Pa., March 2, aged 32, after a long sickness.

**Charles H. Newell, M.D.** College of Physicians and Surgeons, Chicago, 1900, died at Lynch, Neb., February 20, of pneumonia, aged 26.

**Theodore H. Parks, M.D.** College of Physicians and Surgeons, New York, 1860, died at his home, Ilwaco, Wash., February 28.

**Robert Tabney Ball, M.D.** College of Physicians and Surgeons, Baltimore, 1881, died at his home in Baltimore, February 25.

**William T. Akins, M.D.** Medical College of Fort Wayne, Ind., 1878, died, March 6, at his home in Chicago, aged 61.

## Married.

JOHN C. ANDERSON, M.D., Omaha, to Miss Myrtle Boyes, of Seward, Neb., March 3.

WILLIS M. METZLER, M.D., to Miss Lola A. Cross, both of Vanlue, Ohio, February 23.

W. E. STEWART, M.D., to Miss Dolores E. Sharp, both of Stratton, Neb., February 20.

THOMAS W. O'REILLY, M.D., St. Louis, Mo., to Miss Blanche Day, of Saginaw, Mich., March 5.

BENJAMIN D. OSBORNE, M.D., Waldo, Ohio, to Miss Stella Gast, of Prospect, Ohio, February 27.

HENRY H. MITCHELL, M.D., Muldoon, Texas, to Miss Eula Ragsdale, of Wharton, Texas, February 19.

ALFRED HENRY EASTERLING, M.D., Athens, Texas, to Miss Margaret Mitchell Wolford, of Cuero, Texas, February 19.

IRVING R. SCHOONMAKER, M.D., Hallstead, Pa., to Miss Edith Daniels, of Scranton, Pa., at Binghamton, N. Y., February 27.

CHARLES WILLIAM HATGENS, M.D., Hot Springs, S.D., to Mrs. Richard H. Hunt, of New York, at South Bend, Ind., February 19.

## PHILADELPHIA OBSTETRICAL SOCIETY.

*Regular Meeting, held Feb. 6, 1902.***Recurrence of Shoulder Presentation.**

DR. FRANK C. HAMMOND read a paper entitled "Shoulder Presentation Occurring Twice in the Same Patient." The woman, aged 35, was first seen in consultation in her fifth labor, previous labors having been normal. The position of the fetus was right dorso-anterior, the fetus being dead with the right arm prolapsed. Podalic version was done, under chloroform anesthesia, the after-coming head being readily delivered by the Viet-Smellie method. The patient made an uninterrupted recovery. Just about one year after the above-mentioned labor, Dr. Hammond examined the same patient and found her near the end of her sixth pregnancy, with the child in the right occipito-anterior position, vertex presentation. Ten days later he was again summoned to the patient, then in labor. The attending physician stated that, during a strong uterine contraction, the amniotic sac had ruptured with a resultant prolapse of a flexed arm and the funis. The right elbow was found presenting, and the prolapsed cord beating feebly. Pulsations ceased while preparation was being made for delivery. Podalic version was again accomplished, but the after-coming head was arrested at the superior strait and resisted efforts at delivery by several methods. The head was finally delivered by the high application of forceps, the latter being easily done. The etiological factors were a pendulous abdomen, relaxed uterine walls, and a comparatively small fetus in both instances.

DR. CHARLES A. BARNES discussed the paper, citing two cases of shoulder presentation which he had recently treated by podalic version.

**Genital Malformations.**

DR. E. E. MONTGOMERY's paper with the above title referred to cases that had come under his personal observation. One was a young woman, aged 23, who came to him in December, 1899, to determine the advisability of undergoing an operation for the construction of a vagina. Examination revealed no trace of vaginal structure. As the patient was engaged to be married, the writer decided to undertake the construction of a vagina. This was done by transverse incision and blunt dissection between the bladder and rectum. A cavity was thus constructed  $2\frac{1}{2}$  inches in depth. This cavity was lined partially by flaps formed through splitting of the labia minora, and partially by skin flaps two inches long, one from each thigh. The cavity was then packed with iodoform gauze which was not removed for nearly a week. The grafts all held, and at the end of two weeks a glass vaginal plug was substituted for the gauze.

In January, 1902, the patient came to the author suffering with appendicitis and the appendix was removed. Since the patient had suffered much from menstrual molimina request had been made that the ovaries also be removed. The right ovary was found connected with a very tortuous tube which arose from the cornu of the uterus. The latter was about one and a half inches long with a rounded fundus. The left ovary and tube were found well to the left side of the pelvis, springing from a rudimentary cornu a scant inch in length. Both ovaries and tubes were removed. The two uteri were only connected by a slightly thickened band. The structures appeared to have developed from widely separated Müllerian ducts which had in no part coalesced. Their lower portions had become obliterated without the vagina and cervix being developed. The vagina, which had been constructed two years previous, seemed of good size externally, and was found to be a scant two inches in length, although the vaginal plug had not been worn for over a year.

Dr. Montgomery cited another case, an unmarried woman, who suffered intensely with dysmenorrhea and was discovered to have a double vagina with a cervix in each. Abdominal incision disclosed a bicornate uterus united at the cervix, but with two separate cervical canals. The right cornu contained several myomata, one of which projected by a teat-like process into the internal os—undoubtedly the cause of the severe dysmenorrhea. The other horn also contained myomata.

The speaker last summer operated upon the wife of a physician for a large myomatous growth. She had borne two children at term. While doing hysterectomy by the abdominal route, in separating the vagina from the cervix, the operator cut into a sac, at first thought to be the bladder. On close observation this cavity was found to communicate with the uterine cavity by a separate os. Here had been a uterus biseptus, one side of which communicated with a blind vaginal pouch. The uterine septum had been destroyed during pregnancy. Later, this blind pouch became several times its former size and formed a distinctly fluctuating tumor. This was incised and evacuated by the vagina. The partition between the sac and the normal vagina was cut away and the mucous surfaces united, with satisfactory result. The writer once examined a patient in which a peculiar bridge hung between the labia extending from the anterior to the posterior vaginal wall. This was the remnant of a vaginal septum, the superior portion of which had been destroyed by her labor. Recently, in dilating the uterus of a young woman, the bougie passed over to the left side, and the curet passed over what seemed to be a growth as a tortuous canal. Upon opening the abdomen, a bicornate uterus was disclosed. In this case the cornua had a common cervix and cervical canal. These cases, the speaker asserted, present some of the difficulties of accurate diagnosis, and are sometimes instructive from the standpoint of the therapeutics. The paper was discussed by Dr. F. Hurst Maier.

**Rectal Cancer.**

DR. WILMER KRUSEN read a paper entitled "A Case of Cancer of the Rectum Operated upon by Murphy's Method."

Out of 7878 cases of carcinoma collected by Williams from London hospitals, 499 had their initial seat in the large intestines, 401 of these involving the rectum. The case operated upon was Mrs. P. M., aged 68. Patient was a well-preserved woman for her age, but entered the hospital complaining of extreme constipation with great weakness and loss of appetite. Within the last two years she had had several hemorrhages from the rectum. Defecation was very painful at times. On examination, an annular stricture was found with an ulcerating mass on the rectal wall, about three centimeters above the external sphincter, and a diagnosis of carcinoma was made.

Operation was done as follows: An incision was made vertically in the middle line through the posterior vaginal wall down to the rectum. The posterior vaginal wall was dissected laterally from its attachments, and the anterior rectal wall exposed. It was not necessary to invade the peritoneal cavity. The rectum was divided transversely above the growth and the proximal end of the rectum was grasped with four forceps which controlled all bleeding and indicated the lumen of the bowel. The involved portion of the rectum was then excised just above the external sphincter, which was uninjured. The bowel was then drawn down and sutured with fine chromicized catgut through the anal opening to the narrow collar of healthy tissue which remained around the anal orifice. A large rubber drainage tube was introduced into the rectum. The vaginal incision was then closed very much as in performing a Hegar's perineorrhaphy. Convalescence was uneventful and at the time of writing there has been no recurrence of the disease.

By permission of Dr. E. E. Montgomery, the writer reported a second case similar to the first, with the exception that a semilunar incision was made posterior to the anus down to the rectum, and that the sphincter was cut through anteriorly. The former served for drainage after operation; the ends of the sphincter were united by sutures of catgut. The paper closed by an enumeration of the advantages of the operation as summarized by Murphy in his original paper. The paper was discussed by Dr. Montgomery.

At the business meeting of the Society, a resolution was adopted to the effect that abstracts of papers read before the Society should be given to various medical journals; and that the authors of papers should be free to publish them, with the discussion, in whatever journal they may see fit.

# NEW YORK COUNTY MEDICAL ASSOCIATION.

*Stated Meeting, Feb. 17, 1902.*

President, Dr. Parker Syms, in the Chair.

## Management of Normal Labor.

DR. BERNARD COHEN, Buffalo, opened the Symposium on Obstetrics with the above-mentioned paper, and laid special stress on the importance of medical supervision throughout pregnancy, and of pelvic examinations prior to confinement. The urine should be examined once a month up to the eighth month, and then weekly, the quantity of urea and indican excreted being included in this examination. The physician's hands should be scrubbed with green soap and immersed in a 2-per-cent. solution of lysol prior to making a vaginal examination, and the instruments should not only be made sterile but so placed as to keep them sterile. He favored the moderate use of anesthesia during labor. The patient should be kept in bed for 12 days and should not be allowed to go around the house until the third week.

## Use and Abuse of the Forceps.

DR. EDWARD A. AYERS read this paper, claiming that about 1 case in 25 is benefited by the proper application of the forceps. An indication for their use, to which there was hardly an exception, was a slowing and weakening of the uterine contractions and a decided rise in the pulse rate. The traction should not only be intermittent but the blades should be relaxed after each traction. In expert hands the ordinary forceps would give 90 per cent. of the traction in the axis of the inlet, but in difficult cases it was important to secure the other 10 per cent., and hence in these the Tarnier axis traction forceps should be employed. The use of Reynolds' traction rods and similar makeshift applications to the ordinary forceps lacked the efficiency of the true axis traction instrument and were not without danger. It was easy to show that when the thighs are flexed the tension on the outer portion of the perineum is increased, and hence the practical suggestion to extend the patient's limbs when the head reaches the vulva.

## Diagnosis and Treatment of Puerperal Sepsis.

DR. FREDERICK HOLME WIGGIN commented upon the fact that although it had long been known that puerperal fever was another name for wound infection, the mortality in every-day private obstetric practice was as high as fifty years ago. If the pulse of the puerperal woman rose above 90 and the temperature above 100.5 F., and remained so for twenty-four hours, it was the duty of the physician to at once search carefully for the cause. If not on the alert, the presence of a general peritonitis might be the first thing to attract the physician's attention. It usually occurred between the third and seventh day. Malaria and typhoid fever could be excluded by examination of the blood, and the nature of the puerperal infection determined by bacteriological investigation. The birth canal should be inspected for evidence of infection, and the practitioner should not hesitate to explore the uterus if it seemed necessary, and treat this cavity promptly and energetically, for, if this were done, the septic process could usually be controlled. Retained secundines should be removed, the cavity cleansed by the use of hydrogen peroxid and then Monsell's solution applied. If pyemia occurred, it was possible that life might be saved by an abdominal section. In advanced cases of puerperal sepsis our main reliance should be on an abundance of nourishing and easily assimilable food and the free use of copious hot saline infusions.

## Venesection and Transfusion in Puerperal Eclampsia.

DR. ROBERT ABRAHAM said that he had been led to adopt the treatment indicated by the title of his paper by the remarkable effect noted in an apparently desperate case of puerperal eclampsia, resulting from the occurrence of a profuse post-partum hemorrhage. His usual practice was to remove about 20 ounces of blood by venesection, and then immediately inject high up into the colon about three quarts of hot saline solution. Four cases were cited as examples of what could be accomplished by this means. The rationale of this treatment was that it removed considerable toxic material, relieved the

intense cerebral congestion, induced free sweating and urination, and, by causing thirst, encouraged the patient to drink water freely, and so still further stimulated the emunctories. This combination of venesection and saline infusion was comparatively new, although venesection alone had long been a recognized mode of treating eclampsia. If the patient were on the verge of serious collapse it was better to introduce the saline infusion directly into a vein.

DR. RALPH WALDO said that he had never seen a case of puerperal sepsis in which he was willing to do a hysterectomy. His treatment of hospital cases consisted in thorough exploration of the uterus if the os were patulous, and the use of the dull curette.

DR. WILLIAM R. PRYOR also expressed his disapproval of hysterectomy as a surgical procedure in cases of puerperal sepsis. Curettage of the septic uterus had a mortality of 20 per cent., but curettage of the putrid uterus was a comparatively safe and simple procedure. His own method of treating puerperal sepsis consisted in isolating the infected uterus by a packing of 5 per cent. iodoform gauze, after curettage, and then counteracting the resulting iodism by the use of saline infusions.

DR. GEORGE TUCKER HARRISON paid a glowing tribute to the memory of Semmelweis, to whom modern obstetrics owed so much. The cases of sapremia would recover almost without treatment, but the more virulent forms of puerperal sepsis were not readily controlled by any known treatment.

DR. S. MARX characterized cases of sapremia as those having a high temperature, a low pulse and a foul uterine discharge. Undoubtedly there was in such cases a positive indication for curettage, but it was utter folly to use any form of curette in cases in which there was no reason to believe there was in the uterus any material demanding removal. While his experience with Marmorek's antistreptococcus serum had been most disheartening, he had more recently secured some decidedly encouraging results from serum freshly prepared in this country. He had occasionally employed in cases of eclampsia the method advocated by Dr. Abraham. Where it was indicated, there was usually also need to empty the uterus; hence, it was convenient to allow the bleeding to take place from the uterine sinuses instead of resorting to venesection. He had known very severe attacks of eclampsia to occur while the patient was so thoroughly under the influence of veratrum viride that the pulse was down to 60.

DR. L. ZWISLOCK, speaking of the necessity for accuracy in diagnosis in cases of puerperal sepsis, called renewed attention to a symptom that he had found occasionally useful—a peculiar luster of the eye.

DR. BERNARD COHEN was disposed to attribute a good deal of the puerperal sepsis to the fact that obstetricians were so poorly paid for their services that they could not make use of their best efforts. He believed that the average obstetric fee throughout this country was less than \$10. The general practitioner was compelled to attend obstetric cases in the course of his daily routine, and hence it was not uncommon for him to go from scarlet fever or other infectious or septic cases directly to the lying-in chamber.

DR. E. A. AYERS thought one of the great causes of puerperal sepsis was the length of time of the exposure to infection, which was certainly vastly greater than in the operations of general surgery. He condemned the prevalent practice of resorting to chloroform in every case of puerperal eclampsia, often just when the patient most needed oxygen. He recommended the use of anticonvulsives and such measures as would stimulate the processes of elimination. Where the brain was threatened by the enormous intracranial pressure, venesection was certainly indicated, but there were many other cases of puerperal eclampsia in which Dr. Abraham's method of treatment was inapplicable.

DR. WIGGIN, in closing, said that he felt that Dr. Pryor's method of treatment was irrational, for, although iodine acted on the products of bacilli it was not itself directly bactericidal; and the only benefit from opening the cul-de-sac and packing with gauze was that it caused the formation of adhesions.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Treatment of Stye (Hordeolum).

Dr. Casey A. Wood, in *Med. Standard*, states that styes are more often seen in young people and are the sign of a general disturbance of health. In many cases they are the symptoms of eye strain, resulting from an error in refraction. In the earlier stages before pus has formed he advises pulling out the eyelash which runs through the stye and touching the swelling with pure carbolic acid or tincture of iodine. Otherwise the stye should be opened and contents evacuated. Warm fomentations or hot stupes may be applied to relieve the pain and promote suppuration, and in a day or two a mild mercuric ointment should be rubbed over the diseased part. The following is recommended by him:

R. Hydrarg. oxid. flav. .... gr. ii 13  
Vaselin. puri ..... 3i 30

M. Sig.: Apply locally once or twice daily and rub in well.

Styes very frequently arise in anemic subjects and chlorotic girls. In such cases he recommends proper diet and fresh air, and the following as a tonic:

R. Tinct. ferri chloridi  
Acidi phosphorici dil.  
Tinct. rhei, aa ..... 3i 3 75  
Quininae sulph. .... gr. iii 19  
Liq. strychn. .... 3ss 15  
Syr. simplicis, q. s. ad. .... 3viii 248

M. Sig.: One teaspoonful three times a day in water.

### Blepharitis Marginalis.

In cases of blepharitis marginalis, which involve the borders of the lids and is eczematous in nature, he recommends the removal of the crusts; in order to do this sometimes the eye lash has to be removed also, which will prevent the reformation of the crust. Otherwise, the crusts may be soaked with the following solution, and easily removed:

R. Sodii carbonatis ..... 5ss 1 90  
Aq. destil. q. s. ad. .... 3iii 93

M. Sig.: Apply locally to the crusts.

After the removal of all the scabs, an ointment similar to the following should be applied and thoroughly rubbed into the edges of the lids:

R. Hydrarg. oxid. flavi. .... gr. ii 13  
Ung. aque rosæ ..... 3i 30

M. Sig.: Apply locally and rub in well at bedtime.

The following solution containing boric acid should be applied several times during the day:

R. Acidi borici  
Sodii biboratis, aa ..... gr. xv 1  
Aq. rosæ ..... 3ii 7 50  
Aq. destil. q. s. ad. .... 3i 31

M. Sig.: Apply locally several times a day.

### Turpentine as an Antiseptic.

According to the *Med. Record*, glycerinated turpentine may be used with success as an antiseptic in the treatment of wounds. Dr. Kossobudsk fills a sterilized bottle with glycerin and adds a small quantity of turpentine. This should be well shaken and allowed to stand for two days; then he adds a small quantity of a 5 per cent. solution of hydrogen dioxide; it is then ready for use. As an antiseptic it checks excessive secretion when applied to wounds, relieves pain and swelling, and promotes the healing process. This action is thought to be due probably to the oxygen liberated and partly to the properties of the turpentine.

### Gastro-enteric Infection of Infants.

Zahorsky, according to the *Med. Standard*, commences treatment with a dose of castor oil or mild chlorid of mercury, and

in severe cases he orders colonic flushings. He also advises the exclusion of a milk diet, giving water only for a few hours. Later he recommends starchy gruels, egg albumin and veal or mutton broth. He does not place so much reliance in gastrointestinal antiseptics, stating, however, that they may inhibit bacterial growth. He regards bismuth as the best drug, which may be combined with other antiseptics as follows:

R. Bismuthi subnit. .... gr. lxxx 5  
Bismuthi salicylatis ..... gr. xx 1 33  
Syr. rhei arom. .... 3ii 16  
Aq. q. s. ad. .... 3ii 62

M. Sig.: Take one teaspoonful every three hours.

Sometimes he combines resorcin with the bismuth as follows:

R. Resorcin ..... gr. xx 1 33  
Bismuthi subnit. .... gr. lx 3 75  
Syr. zingiberis ..... 3ss 15  
Aq. q. s. ad. .... 3ii 62

M. Sig.: One teaspoonful every two or three hours; or:

R. Creosoti ..... m. iv 25  
Bismuthi subnit. .... 3i 3 75  
Syrupi acaciae ..... 3i 31  
Aq. menth. pip. q. s. ad. .... 3ii 62

M. Sig.: One teaspoonful every three hours; or:

R. Guaiacol carb. .... gr. x 66  
Bismuthi subcarb. .... gr. xl 2 66  
Pulv. arom. .... gr. i 106

M. Ft. chart. No. x. Sig.: One every three hours.

The nutrition should receive the proper attention. Starvation may be proper for two or three days, but later food, consisting of proteids and carbohydrates, must be supplied.

### The Uses of a Combination of Camphor and Menthol.

L. S. Somers, in *Merek's Archives*, recommends the combination of camphor and menthol in different strengths in liquid petrolatum as a local stimulant to the nasal mucous membrane. He recommends the following combinations in nasal and pharyngeal disorders by dropping them into the nose with a pipette:

R. Camphor-menthol ..... m. x 66  
Olei eucalypti ..... m. x 66  
Olei petrolati q. s. ad. .... 3iv 120

M. Sig.: A few drops into each naris when there is local congestion of the nasal mucous membrane; or use as spray; or:

R. Olei eucalypti ..... 3ii 3 75  
Olei cassia ..... m. xl 2 66  
Olei gaultheria ..... m. xl 2 66  
Camphor-menthol ..... m. xl 2 66  
Olei petrolati q. s. ad. .... 3iv 120

M. Sig.: Use as a spray to stimulate the mucous membrane in case of chronic pharyngitis associated with dryness of the membrane.

In cases of subacute and chronic rhinitis, before there is permanent tissue change, he recommends the following:

R. Cocaina hydrochlor. .... gr. ii 13  
Olei cassia ..... m. x 66  
Camphor-menthol ..... m. xv 1  
Olei petrolati ..... 3ii 60

M. Sig.: Use as a spray two or three times a day.

### Treatment of Acute Gastralgia.

According to Short, as noted in the *Ther. Gazette*, gastralgia is essentially a condition in which the patient should be treated and not the disease. The functional activity of the stomach is not at fault, so that helps to digestion in the way of pepsin, etc., are of no benefit. A complete change, with alteration of occupation and freedom from worry, will often stop the attacks. If this is impossible, the best thing to do is to give the stomach complete rest. This should be done by keeping the patient in bed and feeding him either by the rectum, or if orally, by giving as little as possible. He recommends active purging early in the trouble. For the attacks themselves morphin or cocain may be given in a draught. Sharp counter-irritation over the stomach by blistering is often very useful, just as in other forms of neuralgia. He recommends in some cases the application of the faradic current to the epigastric

region for a few minutes at a time to relieve the pain. Increase the current gradually until actual pain is produced if no inflammatory condition is present.

#### Hemorrhage of the Bowels in Typhoid Fever.

A. Thomson, of Adrian, Mich., in *Mercer's Archives*, recommends a tablet containing gr. 3/4 of plumbi acetate and gr. 1/4 of pulverized opium, which should be given every half hour, or oftener if the case is urgent. Bismuth subnitrate or the subgallate is of great value as an antiseptic and aid in quieting the bowels. The bowels should not be evacuated for forty-eight or seventy-two hours, after which time an enema may be carefully administered. In cases of violent peristalsis and diarrhea hypodermic injections of morphia may be resorted to. Sometimes tannin, lead acetate and bismuth subnitrate in combination are quite effective. The application of the ice-coil to the abdomen is of great service in relieving the hyperemia and reducing the temperature. Astringent enemata are of no avail as they do not reach the location of the trouble. Castor oil is a safe cathartic and has proved very safe in his hands as a cathartic in this condition.

### Medicolegal.

#### Care Required of Oculist as Physician—Expert Fees.—

The Supreme Court of Louisiana says, in the malpractice case of *Stern vs. Lang*, that the rule is well settled that the oculist who treats a patient must exercise in that regard the care and skill usually exercised by oculists in good standing. He may be rendered liable for his gross mistakes. This was an action against a reputable oculist of large experience to recover damages for the alleged unskilful and negligent manner in which he, as a physician, performed the duty he had assumed. In other words, it was for personal injuries alleged to have been sustained by reason of negligence and want of skill on his part in the method he followed in removing a tumor below the left eye. But it was not shown by a preponderance of testimony that he, through want of skill or negligence, committed a mistake for which he could be held pecuniarily liable. Experts testified that he followed the established practice, and it was not shown that he committed a gross error, the proximate cause of the injury of which complaint was made. Wherefore, on the ground that the law and the evidence was in his favor, the Supreme Court affirms a judgment which he obtained below. It says that the result of the treatment is not all that is necessary to a recovery of damages. It must be made evident that there was negligence or want of skill. Because there was intense pain felt by the patient after an incision, it says that it did not necessarily follow that it was owing to the negligence or unskilfulness of the physician. It remains that one who is suffering while undergoing a surgical operation is not always the best judge of the cause of the pain he feels. With reference to the complaint of the patient that the physician sought to lull his anxiety (which was natural) about his eye by telling him to be patient and let nature act, and in time it would be all right, the court does not think there was anything in this for which the physician could be held liable. Objection was made to three witnesses summoned by the physician being allowed \$25 each, as experts, and the fees taxed as costs. Louisiana Act. No. 19 of 1884 provides for compensation to be fixed by the court where the testimony requires special study and experience, and the amount of compensation is in great part left to the judge. And, in upholding the allowance in this case, the Supreme Court says that the number of expert witnesses was not excessive, in view of the importance of the issues. It takes it as well settled that it is within the court's power to determine the amount of the compensation; also to restrain the litigant, and keep him within proper bounds, who summons or attempts to summon uselessly a number of expert witnesses.

#### Medical Services for Infant—Charging Wrong Person.

The Supreme Court of Mississippi says that in the case of *Williams vs. Bonner* the former was called as surgeon and physician by J. L. Bonner to attend upon his minor daughter,

Ruby Bonner, who lived with him, some 10 miles in the country. Ruby was involuntarily shot by her own hand, was seriously wounded, and her life despaired of. The doctor's bill for \$107.50 was agreed to be reasonable. He charged the account when made simply to J. L. Bonner, who declined to pay it, and was admittedly insolvent. But J. L. Bonner was the guardian of Ruby, who had a small estate in his hands, and the Doctor brought this suit, in chancery, against him as guardian. The defenses were: 1, that the Doctor having charged the account at first to J. L. Bonner individually was precluded from recovering the same of him as guardian; 2, it was said that Bonner could not, as guardian, contract to pay any sum of money, so as to encroach upon the capital of the estate of the minor in his hands, and therefore a suit could not lie against him as guardian under the circumstances of this case. The decision was against the Doctor in the lower court. But that is reversed by the Supreme Court. The latter says that it regards it as a matter of small moment that the account was first charged against Bonner individually. When all the facts and circumstances relating to the matter and to the persons connected with them were made known to the Doctor, he was then at liberty to charge his account as right and justice dictated. Continuing, the Supreme Court says that the doctrine relating to the duties of a trustee at common law (and in this category the guardian stands to his ward) requires him, when the life of the beneficiary is put in competition with the expenditure of his property, to sacrifice the latter, if need be, for the former. That medical services are necessities to an infant may not, upon the authorities, be questioned; and that an infant himself (there being no other to do so) might call in a surgeon, and bind his estate for a reasonable fee, can not be denied, and what an infant himself might do, this court thinks a guardian could do for him. The general rule undoubtedly is that a guardian may not ordinarily exceed the income of the ward in his maintenance and education, without a previous order of court therefor. But there are exceptions to the rule; and in a case where the court, if it had foreseen the event, would have made an allowance therefor, though exceeding the income of the estate, there the guardian, of his own authority, and without previous authorization, may make the necessary expenditure. Assuredly, adds the court, this case, not to be anticipated by human wisdom or foresight, in which the despair of life of the ward called for aid from the principal of her own estate, and which aid none other would render, was one of the cases covered by the exceptions.

#### Liability for Spread of Smallpox by Escaped Patient.—

The Supreme Court of Texas takes up the consideration of the case of the *Missouri, Kansas & Texas Railway Company of Texas vs. Wood*, accepting it as settled that the company's local surgeon had been duly authorized to take charge of an employe who had the smallpox. This being so, the principal question before it was whether the negligence of such surgeon in employing an incompetent nurse or attendant for the patient, and the negligence of such attendant in permitting him to escape while delirious, rendered the company liable for the damages sustained by a party by reason of the smallpox being communicated to him and his family by such patient. Counsel for the company argued that the quarantine of the patient was a public duty, which the city might have taken in hand without liability for the acts of its officers, drawing therefrom the conclusion that for performing the same acts the company was entitled to the same immunity. But the Supreme Court says that the company did not represent the State of Texas, and was not entitled to the immunity from liability which is accorded to the state. Then, the proposition was urged that the company owed no duty to the party claiming damages, and that therefore there was no liability at his suit for the patient's escape. But the court holds that this case belongs to the class where the duties are intended to benefit the individuals composing the public, because whatever affects the health of the community necessarily affects the individual members thereof; and that, when the duty to prevent the spread of a contagious disease rests upon a private corporation or person, an obligation arises in favor of each member of the commun-

ity, and a right of action exists in favor of him who suffers from its breach. And it holds that whenever the duty of restraining another arises, and the power of control over him exists, liability will follow upon a failure to perform the duty. If the company had undertaken to keep a horse known to be affected with a contagious disease at the same place and by the same means, and the horse had been permitted, through the negligence of the attendant, to escape, and had communicated the disease to a horse, the property of the party asking damages in this case, there would have been no doubt of the company's liability for the damages. If there was a sound reason for denying to him as great security for his wife and children against the diseased man as would have been accorded to him in favor of his beasts against a diseased horse, the court says that it had not been suggested by counsel, and that it was unable to discover any tenable basis for the distinction. The amount of diligence which was required of the company depended upon the character of the disease and the danger of communicating it to others. In the end, the court says that the object of placing this patient in a tent and supplying a nurse and guard for him was not alone to care for and to provide for him, but also to protect the public against infection by contact; and when the railway company undertook to treat him for the disease, and to care for him at the place designated by the mayor of the city, it assumed the duty of using ordinary care to prevent the patient from exposing himself in delirium, or from being exposed otherwise, so as to communicate the disease to other persons; and, having failed, through the negligence of its employees, to use such care, and by reason of its negligence the patient having escaped and communicated the disease to this other party's family, the company was liable for the damage caused thereby. Hence, the question propounded was answered in the affirmative.

1. **Smallpox.**—Shepherd describes certain varieties observed and gives observations from the recent epidemic of smallpox. A few of these may be mentioned. In some cases there was a picture of corymbose or confluent patch type of the disease, and in some other cases the eruption toward the close of its development became surrounded by red and very much indurated bases; the solid parts of the pocks remained, and were much raised above the surface of the integument; they continued to grow until they formed papular excrescences resembling warts, which were hard to reduce. He suggests the tubercular diathesis in these cases. The most frequent complications were eye affections; conjunctivitis in about ten per cent. In a few cases there was marked pyalism in the beginning of the vesicular stage, which continued into the late scabbing stage. In others there were enlarged submaxillary and sublingual glands. Secondary infections seem to attack certain cases, aggravating the cutaneous lesion and prolonging convalescence. In the two cases in which the disease occurred the second time the individuals claimed to have had smallpox in childhood and showed pits in evidence. They both had well-marked, though discrete, cases in the second infection.

2. **Follicular Tonsillitis.**—In this article Brown describes follicular tonsillitis and remarks that it is one of the most satisfactory diseases to treat. He finds the best results from the use of salicylate of soda and gives coal-tar products to relieve headache and pain. The points which he has endeavored

to present are summed up as follows: 1. That follicular tonsillitis is not caused by a single microbe, but that many well-known micro-organisms are capable of causing it. 2. That the symptoms of tonsillitis are partly caused by an exaggeration of its function. 3. That under the stimulus of infection the lymph corpuscles in the adenoid structure of the tonsil produce an antitoxin that is antagonistic to invading germs. 4. That the characteristic symptom is an exudate having no texture and non-adherent. 5. That the presence of the Klebs-Loeffler bacillus is not positive evidence that the disease is not a simple follicular tonsillitis. 6. Lastly, that there seems to be some relation between follicular tonsillitis and the infectious diseases which is not yet properly understood; that whatever the function of the tonsil, it seems in disease to endeavor by its activity to assist nature in eliminating infection. He says that many cases diagnosed as diphtheria are really follicular tonsillitis. He thinks that antitoxin has been given ten times in follicular tonsillitis where it has been given once in diphtheria. This does not mean that he depreciates antitoxin, which he considers the supreme remedy in diphtheria.

**6. Suturing the Head of the Humerus to the Acromion.**—In a case of old shoulder dislocation which had resisted numerous attempts at reduction, a nearly semilunar incision was made by Beck, beginning at the acromion and running over the intertubercular sulcus and extending vertically alongside the anterior surface of the arm, exposing both the joint and the acromion. After careful dissection of the adhesions the humerus was successfully rotated into the glenoid cavity, but there was a pronounced tendency to forward displacement which could not be overcome by additional exposure. He therefore fastened the head of the humerus in the cavity by sutures to the acromion after having drilled a hole through the acromion as well as through the head of the humerus. The latter was found to be very soft; a skiagraph taken two weeks later showed the joint in a good condition; good results seemed to have been secured. It seems to him that this procedure is far superior to resection of the head of the humerus, as advised by many surgeons, no force being required, and by it laceration of muscles, blood vessels and nerves is easily avoided.

**8. Acute Pelvic Suppuration.**—The conservative treatment of pelvic suppuration is the subject of Polak's article. The statements and claims he gives are summarized as follows: 1. Early diagnosis in pelvic suppuration is imperative. 2. When the diagnosis is made, operate. 3. The vaginal operation is the one of choice. 4. When it is done early with strict asepsis it is curative and may preserve the function of the woman's organs. 5. It improves the patient's condition, makes subsequent operation easy, prevents rather than causes adhesions. 6. It may be used for diagnosis in obscure cases without shock or injury to the patient (if aseptically performed). Finally, this operation may be applied to every acute suppurative condition within the pelvis.

**9. Ventrofixation.**—Pedersen suggests an operation on the principle of McBurney's intramuscular method of suturing the abdomen in appendectomy and remarks that the procedure has probably not been described in medical literature. The details as given by him are as follows: 1, exposure of the sheath of the rectus through a median cutaneous incision two or three inches long; 2, strong retraction of the skin to one or the other side; 3, opening the sheath of the rectus about three-quarters of an inch from the median line; 4, liberal loosening of the rectus from its sheath and retraction of it as far outward as possible; 5, opening of the peritoneal cavity; 6, loosening of the peritoneum behind the linea alba; 7, search for large vessels at this point; 8, passage of the sutures as follows: The median edge of the peritoneal wound is seized with forceps and the needle is introduced half an inch away from the middle line; it is next carried through the uterus, emerging beyond the median line on the opposite side; it is then passed forward through the peritoneum, previously loosened as described, and then through the linea alba sufficiently deep to secure a firm hold; the two ends are then seized in an artery clamp; the other suture is passed in the same way and both are tied, so that the knot is extraperitoneal; 9, suture of the peritoneum;

10, restoration of the rectus to its sheath; 11, ordinary layer sutures close the rest of the wound. The result of this operation is that the uterus is suspended in the median line, as in Kelly's original operation, while the scar is lateral to the point of fixation and is itself protected by the healthy rectus muscle, being "staggered." In closing the sheath of the rectus mattress sutures were used, so arranged that they did not pull on a single bundle, but on many bundles of fibers. This was accomplished by passing the needle near the edge on the right side of the wound and emerging quite far from the edge on the left side. Then on the left side it again pierced the fascia near the edge and emerged on the right side far from the edge. When these stitches were tied this arrangement gave perfectly uniform apposition and the advantage of there not being any likelihood of their cutting through at the least strain. Another detail which seemed very advantageous in two cases operated on was the insertion of a retention catheter into the bladder before the uterus was suspended. By this it was possible to inject six to ten ounces of sterile salt solution and indicate the best place for fixing the uterus with the bladder full. This enables one to avoid pressure of the uterus on the bladder for the first few months it is hoped, and in neither of his cases has the patient suffered from this cause.

**10. Leukemia.**—After reporting a case of leukemia, McCaskey notes certain points of interest, the most important one being the preceding existence of chronic colitis of long standing associated perhaps the greater part of the time with catarrhal disease of the small intestine. This, taken in connection with physiologic leucocytosis definitely recognized before the appearance of myelocytes, raises a very interesting question of etiology. The relationship of chronic colitis and leukemia is of interest. He does not consider it evidence as to the possible infectious nature of leukemia, though it is strongly suggestive. Just what is required beyond the toxic action or malnutrition of intestinal origin is not easy to say. It may be spoken of, he says, as a general vulnerability—a peculiar tendency to take on degenerative changes of embryonic type—on the part of the tissue under consideration. If this is unsatisfactory as an explanation it is not more so than the explanation given for the effects of family predisposition in tuberculosis.

**11. Pancreatic Disease.**—In answer to the questions: What criteria do we possess for recognizing gross anatomical changes in the pancreas? What means have we for appreciating disturbances of function of the pancreas? What are the diagnostic features or the more important changes in the pancreas? Thayer goes over the data in our possession and remarks: "In conclusion, it may be said that while we possess as yet no diagnostic symptom of pancreatic disease, unless indeed further observation should confirm the possibility of the demonstration in acute pancreatitis, of the fat-splitting ferment in the urine, yet clinical and pathologic experience have taught us certain combinations of symptoms which justify a diagnosis in various forms of pancreatic disease. Acute pancreatitis should be recognized in many instances. The importance of an early recognition of these cases which go on to extensive necrosis and to suppurative parapancreatitis is easily appreciable. Chronic interstitial pancreatitis is to be suspected under the following conditions: 1. Instances in which glycosuria develops in an individual with chronic cholelithiasis. 2. In cases of glycosuria in association with cirrhosis of the liver. 3. In glycosuria in the course of hemochromatosis. 4. In glycosuria following attacks suggestive of pancreatic colic. Pancreatic lithiasis is recognizable only when calculi are found in the stools. Cysts of the pancreas are usually to be recognized on account of their location. Primary cancer of the pancreas is often latent. The presence of obstructive jaundice with distended gall-bladder and rapidly developing cachexia, in association with little or no hepatic enlargement, is suggestive of this affection. Fatty stools—in the absence of diarrhea or jaundice—together with indications of interference with the digestion of albuminoids, are valuable confirmatory evidence of deficiency or absence of the pancreatic secretion."

**13. Peritonitis.**—Smith's article is in effect a plea for operative treatment of peritonitis; he thinks the high mortality in

operative cases has been due to late operations. He believes in the use of flushing with saline solution and drainage. He says that in these cases the abdominal incision should be left as open as is consistent with retaining the abdominal contents. Silkworm gut sutures to the peritoneum approximating the upper and lower edges of the incision are best, and gauze compresses may be tucked loosely into the gaping wound to hold back the intestines until adhesions have formed. The dressing can be secured with adhesive strips and a many-tailed bandage. After the conclusion of the operative work he dilates the anal sphincter to make the later escape of the flatus as easy as possible. His post-operative treatment consists in the use of strychnia hypodermically in severe cases, rectal flushing with salt solution, morphin to relieve pain, stimulants, and whisky given as soon as it can be borne by the stomach. After the fourth or fifth day calomel may be given in hourly half-grain doses with sodium bicarbonate, Rochelle salts or compound jalap powder as a laxative, followed by turpentine and glycerin enema if required. Nourishment by the mouth is absolutely forbidden for three to six days after operation, and he begins it cautiously with meat broths, withholding milk until the second week in convalescence. The point he specially wishes to emphasize is the surgical procedure, which he thinks we should follow, in view of the fact that acute general peritonitis, as a rule, proves to be fatal when neither irrigation or drainage is employed.

**16. Suggestions to Anesthetizers.**—The following is a recapitulation of Simpson's suggestions in this article: 1. Give the patient your undivided attention. 2. Give the anesthetic slowly. 3. Keep the patient's lower jaw forward. 4. Give the anesthetic most cautiously (especially chloroform) when the stage of unconsciousness is at hand. 5. During deep anesthesia watch particularly the respiration, but also the pulse, eye and color. 6. The rolling of the eyeballs from side to side is the first and most easily observed indication of returning consciousness.

**17. Adrenalin in Anesthetic Solutions.**—From experiments, Elsberg is convinced that the addition of adrenalin chlorid in proportion of 1 to 5000 to 1 to 20,000 solution for local anesthesia has a distinct value in minor operative surgery in that it almost entirely does away with the oozing of blood from the wound. As adrenalin is a cardiac stimulant, he says it has the additional advantage that it will counteract the depressing effect of the eucaïn or cocain; because it keeps the local blood vessels firmly contracted for a number of hours, it will prevent the congestion, and hence the pain which is so apt to follow after the anesthetic effects have worn off.

**19. Early Diagnosis of Pulmonary Tuberculosis.**—The importance of the physician informing the patient as to his condition is the first point noted by Stubbart, who maintains that inasmuch as the patient should co-operate in the treatment this has an important bearing on the outcome. He considers the predisposing factors—the heredity, scrofulosis, defective or insufficient food associated with imperfect ventilation, grief, overwork, frequently recurring catarrh, damp localities, race, shape of the chest, traumatism, former pulmonie or pleuritic disease, chronic catarrhal troubles. Vital capacity, as defined by H. P. Loomis, when found below the normal standard, is a strong predisposing factor. Gradual loss of weight and increased activity of heart action should always lead to a chest examination. Other early symptoms he mentions are a slight hacking cough with or without sputum (first eliminating laryngeal or pharyngeal causes), slight night sweats, slight evening rise of temperature, loss of appetite, weight, hoarseness, tired feeling in the afternoon, blood spitting and even small hemorrhages. A rapid pulse accompanying some of the above-mentioned symptoms, always over 100 or 110, should lead us to suspect tuberculosis. The physical signs should be looked for carefully. Slight flattening of the supra- and infra-clavicular regions with prominent clavicle may be present. Expansion is a rather indefinite symptom. It is well to observe posteriorly as well as anteriorly, but he thinks that chest expansion should not be relied upon, for consolidation may occur before it is prominent. Percussion signs are not always distinct. In

most cases, however, we will get a slightly high-pitched percussion note in the infra-clavicular space and increase of vocal resonance with prolonged expiration. If we have with this a bronchovesicular rather than a bronchial breathing we should suspect tuberculosis. Occasionally we find a cog-wheel respiration, but not as a rule in the early stages. The râles in the early stage are rarely heard. As many of the incipient cases present no expectoration whatever, and if sputum exists bacilli may be absent, bacterial examination of the sputum loses much of its value as a negative factor. If there should be a slight expectoration with bacilli we need go no further before making the diagnosis, but finding none in the sputum is no reliable guide. The tuberculin test he has not found to fill our expectations as a diagnostic test, for it fails in some cases and reactions occur in some syphilitic cases. Examination of the larynx may or may not give us definite information; a slight anemic condition is what may be expected. The blood examination, according to the Loomis Sanatorium experience, shows that pure tubercular disease has very little effect on the blood and that the diplococcus lanceolatus associated with the tubercle bacilli was the primary cause of severe anemia in sixty cases. In tubercular diarrhea it is the drain on the body albuminoids and not the tuberculosis which is the cause of the severe chloranemia. Any slight rise in temperature has not the slightest effect on the hemoglobin. The temperature we get in mixed infection drains the red blood corpuscles of their vitality and lowers their number. In mixed infection with cavity and moist râles and secondary anemia with leucocytosis 75 cases showed the polymorphonuclear cells increased at the expense of the leucocytes, the latter being of the large variety. But when the moist râles disappear and the cavity dries up, the leucocytes disappear. The blood of pulmonary hemorrhages does not show any nucleated red cells. The perfectly normal blood, accompanied by loss of weight and other rational symptoms, should not negatively effect the diagnosis of tuberculosis. The Roentgen rays are mentioned as a valuable test, and he gives special details as to their findings and method. A more or less restricted action of the diaphragm is noticed as an invaluable indication of incipient phthisis. As regards treatment, he remarks that the upper air-passages should always be looked into, as lesions of more or less severity generally exist there. The anemia should be corrected. Hydrotherapy is a valuable factor in the treatment, and exposure to parallel rays from a powerful arc light, followed by static electricity in the form of negative insulation, appears in many instances to improve the nutrition and increase the hemoglobin. Hot-air inhalations and cold sprays are valuable, and there seems to be evidence that the anti-tuberculin serum has some value. Especial attention should be paid to the diet and the condition of the stomach should be looked after, as gastritis and dilatation are common in these cases. He thinks that siphon irrigation and sometimes the Einhorn method of faradization is often imperatively demanded. He suggests that the injudicious use of drugs is often damaging in this particular regard.

**22. The Eosinophile Count.**—Noticing a statement in one of the medical journals that human blood could be differentiated from the blood of animals by the relatively high percentage of eosinophile cells, Wightman has investigated the subject and comes to the following conclusions: 1. That in this series examined eosinophilia may occur in higher percentage in animal's blood than in human blood. 2. That the physical condition of the animal whose blood is to be compared may play an important part in the increase or decrease of eosinophiles present. 3. That in the specimens examined the polymorphonuclear counts were low and the lymphocytes high, exactly contrary to conditions present in normal human blood. 4. That the eosinophile count is not a constant or trustworthy factor in diagnosis, but, on the other hand, is very unreliable and unsatisfactory; and, finally, 5. As a comparative test the eosinophile count is a negative quantity.

**23. Five Maine Murders.**—Thayer's histories of the cases here noticed and analysis of the facts of criminal medical jurisprudence in Maine show that the plea of insanity has very little effect in that state. Insanity there has never been

a cloak for homicide. Within the last twenty-five years there have been at least five cases of homicide in which the doer of the act has been insane before and after he did it, and there is at least a high degree of probability that the act itself was the product of his insanity. Nevertheless, these men have been convicted. These convictions are to be attributed in part to the explicit, lucid, archaic, and rigorous rulings of the courts. The practical working is that in Maine the "only proper legal criterion is to concede irresponsibility only to idiots and maniacs." He thinks the realization of these facts on the part of the courts, the prosecuting officials and the public, together with increasingly accurate knowledge of the nature of mental disease, must inevitably lead to verdicts more just, scientific and humane.

**24. Abdominal Pain.**—Richardson's article is finished in this issue. His conclusions are as follows: When a patient has been siezed with sudden severe abdominal pain, 1. The pain should not be masked by opiates before the surgeon has an opportunity to see the case. 2. The previous history, accompanying symptoms and physical signs must be carefully considered. 3. Careful examination of the thorax and abdomen in all cases of pain should never be omitted. 4. When hemorrhage is suspected, the abdomen should always be explored. If the patient is in collapse and the pulse apparently too weak to allow the patient to undergo exploration, preliminary infusion of salt solution should be made into the veins or under the skin. 5. When the pain is excruciating and the abdomen shows signs of infection, exploration should be made at the earliest possible moment. 6. The seat of the initial pain, as described by the patient and his friends, is a good guide to the incision when, from other symptoms, the surgeon is in doubt. 7. The history and signs other than pain must be relied upon for exact or reasonably positive diagnosis. 8. When some of the rarer abdominal lesions are suspected, exploration should nevertheless be made. Such an exploration may be useless, but if resorted to as a routine procedure in all cases, the greatest possible number of lives would be saved. 9. When there is the least question, the genuineness of the pain should be tested as thoroughly as possible. 10. The pain of an atypical typhoid, of a pleurisy, of a pneumonia, must be guarded against. When typhoid is prevalent in a community the greatest care must be taken lest the surgeon be misled by the pain of such a case. 11. The observer must be on his guard lest he confuse the pain of simple functional disturbances with that of organic disease; he must rely upon the accessory signs of the organic lesion. 12. When in grave doubt as to the significance of pain and other symptoms, the benefit of the doubt should be given the patient by surgical exploration. 13. Finally, when no exploration is regarded as justifiable, pain should be controlled by morphia, by hypnotics, or, if necessary, by general anesthesia. With very few exceptions, however—chiefly cases of renal and biliary colic—the pain that demands general anesthesia demands operation.

**25. Diagnosis of Abdominal Disease.**—The first special point of value to which Jackson calls attention is pain. Nothing is less reliable, but every attack of pain must receive our most careful attention, though it may not be a symptom of serious import. Nausea and vomiting are of the greatest importance and should be carefully considered in the history of any abdominal case. It is rare to find any acute disturbance of the peritoneum without their occurrence. On the other hand these disturbances are not so common in colic or abdominal disturbances from other causes. Another point of value in the history is the occurrence of constipation, obstinate in character, in a patient who has not previously suffered from this symptom. Among the physical symptoms the general appearance may be of much importance. The bright mental condition is in strong contrast to the hebetude seen in many febrile conditions, the pinched and anxious facies, the absence of, or the limited excursion of diaphragmatic respiration and the bending of the knees to relieve extra abdominal pressure. Exploration should be made if there is any suspicion of tumor. A pulsation transmitted to the abdominal wall at or below the umbilicus is always suspicious of tumors interfering with the

aorta. We should always look also for peristaltic contraction of the bowel in the diagnosis of intestinal obstruction. When present it is a sign of much importance. It is not usually difficult to make a diagnosis of excessive fat in the abdominal wall, but mistakes are possible and the simplest method of determining is to take up within the two hands as much as possible, which must be subcutaneous. Tenderness must be sharply distinguished from pain and is of paramount importance. When spasm is added the surgeon must have strong evidence to the contrary to justify him that there is no acute local inflammation. In many cases of appendicitis the evidence of tenderness and spasm at McBurney's point clinches the diagnosis. There is one place in the epigastrium, just below the xiphoid cartilage, where there is always tenderness or a little discomfort, and this should be remembered. Spasm is of even greater importance than tenderness, and the absence of these two symptoms in cases of colic or abdominal pain are most reassuring that the trouble is not dependent upon any inflammatory process. In children it is always the best plan to have the mother or nurse press fairly hard in various parts of the abdomen, and especially over the appendix, to determine whether there is tenderness. We must remember that hard masses of feces may simulate tumors and are often retained in the intestine, though the patient may have had many small loose dejections. A simple diagnostic method of much value in determining between small pleural effusions and enlargement of the liver, or some inflammatory process between the liver and the diaphragm, subdiaphragmatic abscess, is to determine accurately by percussion the upper line of dullness in the chest wall. Then let the patient take a full inspiration and hold the breath. Continue a light regular percussion while the patient inhales and note carefully whether there is any change in the percussion note during the full inspiration. If the dullness is due to fluid in the pleural sac there will be but little change in the upper area of dullness, whereas, if the mass be beneath the diaphragm, good pulmonary resonance will be found at the point previously dull as the expanded lung will extend downward over the subdiaphragmatic mass. This method will usually demonstrate the presence of an enlarged liver, or the rare and always obscure condition of acute suppuration between the liver and diaphragm. He does not think this method is in common use, though it is of much value. The sign which to his mind is of greatest importance in the diagnosis of intestinal obstruction, is the significance of an empty rectum as suggestive of intestinal obstruction, when there has been no movement of the bowels for several days. Of course, its value is greatly increased if, as is usually the case, cathartics and enemata have been given previously without satisfactory results. He has invariably made, since his attention was first called to this sign, rectal examination in cases of suggested bowel obstruction. The finding of blood is of great importance in corroborating the suspicion caused by the discovery that the rectum is free from feces. In consultation he often finds that no rectal examination has been made. An examination of the blood may give us important evidence from the existence of leucocytes in acute inflammatory conditions. Exceptions may occur, but not often; for instance, in severe acute septicemia in a class of cases in which rise of temperature is not found. Cases of this kind, to judge by the pulse and the general symptoms, are evidently very ill, so that the absence of leucocytosis can not lead to error if we only remember that in such cases leucocytosis may not exist. Other cases where it does not occur are rare exceptions. The blood count is of much value in the differential diagnosis of two diseases with similar symptomatology in the early stages, namely, typhoid fever and appendicitis. In the former the leucocytes are diminished, in the latter they are generally increased. Of course, the Widal reaction is of importance, and the blood count is of much value in the elimination of malaria when chills of doubtful etiology are present, but the malarial organism, if present, determines the diagnosis.

**28. Adiposis Dolorosa.**—Dereum reports two cases, one in a male and one in a female. In each case the family and personal history seemed to throw little light upon the cause. There is no mention made in the histories as to alcoholic ex-

cesses. In the man's case there was epilepsy as has been noted in one of the other cases out of the 25 that have been previously reported.

**31. Mental Defectives.**—Barr's paper emphasizes the importance of the institutional treatment for defective children. The evils of home treatment are the impossibility of cure and the evils of atavism; for, the transmission of inherited taint is certain in this class of defectives and they therefore need permanent sequestration. The public notion that asylums and training schools for this class of cases are curative is repudiated by him; there is no cure for that which is not diseased, but was originally absent. What is absent can not be replaced.

**32. Sodium Cinnamate in Tuberculosis.**—Mann reports a number of cases treated by Landerer's sodium cinnamate with benefit. He uses also in most cases strychnia, iron and other general tonics, and holds with Landerer that the process may be summed up by saying that the treatment substitutes an active, aseptic inflammation for an inactive one and the result is rapid cicatrization.

**33. Ice-Pack.**—Roos' rule for employing the ice-pack in cases of typhoid or other febrile diseases where hydrotherapy is employed is to use the thermometer frequently. If the temperature goes above 102.2 he employs the ice-pack. If the urine is negative, with no trace of renal disorder, he gives a little spiritus frumenti before and after the attack, otherwise plain hot milk is used. The mattress is covered with a couple of blankets, on top of which is placed a piece of rubber sheeting covered by another blanket. A sheet and blanket soaked in water at 70 are laid at the side of the bed, and the patient is rolled into them without exposure. A half hour later another sheet and blanket at 60 is substituted, care being taken not to expose the body during the change. At the expiration of another half hour the first sheet and blanket soaked in water at 50 are applied. At this time the axillary spaces, the arms and legs from the middle of the femur down are covered with cracked ice, packed outside the sheets. The operation is once more repeated at a temperature of 40; the entire duration of the pack being two hours. The effect is that of a sedative and general stimulant, sleep follows and the pulse is improved. This method avoids the sudden shock and rough handling of the Brand method and the consequent risk of producing perforation in cases of typhoid ulceration. He thinks no matter how much the Brand method has been valued in the past it will soon be obsolete as this method is learned and adopted by the profession.

**34. Prostatectomy.**—The method advocated by Bryson is not to open the bladder from above, nor to open the peritoneum, but to enucleate from below. The high incision through the abdominal wall into the bladder is withheld to the later stage of the operation, if it is required at all. The enucleation from below also permits a complete prostatectomy and avoids incision of the vesico-urethral isthmus, which is the most serious source of both operative and post-operative hemorrhage. The prostatic substance is entered from the urethral and not from the capsular side. If a small puncture with a blunt instrument is made just behind the ring at the apex of the gland, which requires incision as the bistoury is pushed along the groove of the staff, the finger can be pushed into the small opening, entering the prostatic tissue. The urethra slips backward longitudinally, giving room to work. The entrance is made, not on the floor, but to one or the other side of the median line, always toward the lower lateral segment and a little behind the apex. The excochleating finger is now swept around the outer portion of the overgrowth, out toward the capsule, and back toward the base, care being taken not to tear the urethra by too much force. Care should also be exercised not to tear away too much of the sides and the upper part of the urethral wall. The procedure can be repeated on both sides in the same way. In taking away the middle lobe, if this be found necessary, we may have to tear away a part of the floor of the urethra, leaving a tongue or flap of mucous membrane which we must avoid doubling back into the bladder in the introduction of the drainage tube, subsequently. The little removal of the urethral floor has not done, in his experience, any special damage, but

we must be very careful not to remove any of the roof of the canal and as little of the sides as possible. The drainage tube being introduced through an intact sphincter vesicæ, hemorrhage is completely controlled by packing around it or by irrigation with hot boric acid solution. The tube should be hard so as not to be collapsed by the packing. It is important to leave the capsule of the prostate intact. In his own work the mortality has been reduced from 25 to a little over 6 per cent. The advantages are summed up in: Avoidance of epicystotomy with its attendant evils and dangers; avoidance of opening the prostatic capsule and interference with the vesico-prostatic capsule and plexus; excochleation of the overgrowths from the urethral side. Avoidance of incising the vesical outlet; adoption of the prevesical incision for the purpose of bringing the structures within reach of the finger working in the perineal wound; adequacy of drainage; efficiency of hemostasis, both operative and post-operative.

**38. Artificial Infant Feeding.**—Visanska calls attention to the difference between human and cow's milk and remarks that he has adopted Professor Seibert's method of feeding babies according to weight and not according to age, and gives his reasons for the same. If a child three months old weighs 18 pounds, as it may, while the normal weight for such age is only 12 pounds, and the latter weight is taken as a guide, some five or six pounds of the child will not be properly nourished. He advocates the use of Seibert's formula (*Archives of Pediatrics*, July, 1894), and believes in the filtration of milk through a layer of absorbent cotton as devised by that authority. He gives a chart of his own device for feeding the infant and thinks it has certain advantages. The preparations on the market, he claims, produce an unhealthy growth and are not reliable. Food can be insufficient for the child in two ways, either by too limited amount or by lack of elements essential to nutrition or given in a form not adapted to the feeble digestive powers of infancy.

**39. Eye Defects in Children.**—The eye defects which may cause apparent mental dulness and deficiency in children are reviewed by Bull, who gives them in the order of their frequency. The first is hypermetropia, which makes the patient incapable of sustained accommodative effort for near objects for any length of time, producing pain, headache and incapacity of the child for ordinary close work. The next most frequent is astigmatism which is often the cause of the unjust charge of dulness. This may lead in neurotic children to various apparently irrelevant reflexes and even epileptiform attacks. The third refractive error and the most distressing one is myopia. The mental evolution of the child suffering from recognized or defective myopia is instructive—unable to see what his companions see and jeered at for his failure, he becomes introspective and perhaps perverted in his tastes. Muscular anomalies may also give rise to some difficulties. The effects of squint are also usually associated with some refractive error. Other special defects, which rarely occur, such as congenital cataract lens dislocation, lack of pigment, coloboma and aniridia, are mentioned; in conclusion, he calls attention to an important and altogether interesting defect which has nothing to do with the eye as an organ of vision, but rather with the visual centers in the brain, viz., congenital word-blindness, of which cases have been reported by Hinshelwood and Nettleship. In these, changes have been found in the left supra-marginal convolution and angular gyrus. It should not follow because this has been little noticed heretofore that it is necessarily rare. It may be moderately frequent. Its importance from an educational standpoint is obvious. If the case is curable the remedy will probably be found in methodical instruction in reading begun at as early an age as possible. If it is irremediable the sooner this is ascertained the better.

41.—See abstract in THE JOURNAL of January 4, p. 53.

42.—Ibid.

**48. Typhoid Fever.**—The treatment of typhoid fever here recommended by Boggess consists first of all in diet. He thinks more patients are lost by underfeeding than by overfeeding. The old idea that milk is the sheet anchor must be discarded. He believes it a bad food, but he does believe in buttermilk, and he would give his patients four to eight eggs

in one form or another daily with a quart of buttermilk and good nutritive soups. The diet can be enlarged by various custards, fruit jellies and gelatins. He gives through the disease salol, bismuth subgallate, Beta naphthol, urotropin and occasionally ichthyol, piperin and eucalyptol, with small doses of calomel. He has no fear of the use of laxatives in typhoid and never hesitates at any stage of the disease to give broken doses of calomel, Seidlitz powder, citrate of magnesia or Rochelle salts, preferably in lemon-water. The Brand treatment, while excellent, is not always practicable. He thinks we have to rely sometimes on unintelligent cold sponging or the scientific application of the cold pack. Hot packs he finds in certain cases give as good or better results and are more pleasant to the patient. He has no hesitation in using some of the antipyretics, such as phenacetin, phenalgin and acetanilid, and he insists on the patients taking all the sterile water they want. For hemorrhage he would prescribe absolute quiet and rest, withdrawing all food for from ten to twenty-four hours, hypodermic injections of morphin, cold to the abdominal surfaces, salt solution and ice water enemata. Cardiac asthenia demands alcohol, strychnia, citrate of caffein in full doses and absolute quiet.

**52. Sterilized Vellum for Prevention of Adhesions After Laparotomy.**—Cargile has employed a very delicate vellum prepared from serous membrane to interpose between surfaces prone to adhesion after laparotomy. It is used sterilized, adapts itself closely to the surfaces and is soon absorbed. So far as he has learned he has seen no mention of a similar use of this substance.

**53. Grippal Pneumonia.**—Watkins briefly describes the types of pneumonia complicating la grippe and summarizes that the typical grippal pneumonia differs from the ordinary form: 1. By the slow insidious invasion. 2. By the predominance of bronchitis. 3. The rather low, often remittent temperature. 4. The tendency to heart failure and cyanosis. 5. The frequent absence of rusty sputum. 6. Absence of critical defervescence and strong tendency to delayed resolution. 7. A tendency to wander from one lobe to another and thus involve the apex. 8. Decided fatality and infectiousness to a curiously limited degree. He advises for these cases heart tonics, the early use of stimulants, alcohol, carbonate of ammonia instead of the usual cough mixture expectorants; codein and heroin in elixir terpin hydrate for cough, caution in the use of morphin and no antipyretics of a depressing character.

**60. Cretinism.**—Koplik calls attention to a special stigma of cretins, as he has observed it, viz., the enlarged or prominent antithenar eminence and over the situation of the os pisiformis. This is present in all the cretins he has examined, but he has found it also in other degenerates. He has observed it in children not over three months of age; therefore, it can not, he thinks, be credited to an abnormal use of the hands in creeping. Besides cretins he has found it in hydrocephalic idiots and dwarfs.

**61. Malaria.**—The mild epidemic in the Foundling Hospital, described by Freeman of uncertain nature, seems to resemble prodromic malaria more closely than anything else. This diagnosis was confirmed by one typical case of malarial seizure accompanied by the presence of the plasmodium in the blood, and by the fact that all the 82 children affected recovered promptly with the use of quinin. There were pools of stagnant water adjacent to the room in which these children were during the day, but the conditions were hardly sufficient to account for the malarial attack.

**63. Hare-Lip.**—Ratchford reports a rather strange history of a family in which there were born four girls with hare-lips and cleft palates and three boys without any trace of this peculiarity. A curious fact was that the mother during pregnancy was able to foretell the sex of the children and whether or not they were to be thus deformed, at least that was her belief, and it seems to have been borne out by the facts. Whether her mental condition of depression under this conviction had anything to do with it, of course, is worthy of thought. There was a bad family history of tuberculosis on both sides, but no history of hare-lip. The mother had a high arched palate.

**75. Visual Centers.**—Spiller reports the case of an idiot in which the eyeballs were lacking and in whom the autopsy showed no optic foramina, no trace of optic nerves, chiasm or optic tracts, no sign of external geniculate body, small occipital lobes, the cuneus very small with short calcarine fissure and defective development in optic thalamus and optic radiations. The conclusions which he deduces from this interesting case are given as follows: 1. The chief primary optic center is the external geniculate body. 2. The pulvinar of the optic thalamus is also an important primary optic center. 3. The anterior colliculus of the quadrigeminal body in man has an unimportant relation to the vision. 4. The hypothalamic body, the habenula and the internal geniculate body probably are not parts of the visual system. 5. The cortex of the calcarine fissure may contain nearly the normal number of cell bodies, even though the visual system may be undeveloped. 6. The nerves to the ocular muscles and their nuclei may be developed, even though the visual system is absent. 7. Congenital spastic paraplegia may be the result of deficient formation as regards number or size of the neurons of the central motor system, even though such a deficiency may be difficult to detect by the microscope."

**88. The Technics of Nephropexy.**—Edebohls has personally examined fifty-five kidneys which he had anchored from one to eight years previously, with an average of more than three years since the intervention. Fifty were found solidly anchored; in five the attachments had stretched more or less, or the kidney had followed the movements of the lax abdominal wall, but none had become detached from anchorage. He remarks that his publications on the relations of movable kidney and appendicitis in 1895 attracted little attention at the time, but experience is confirming their correctness, and several surgeons now follow his practice of lumbar appendicectomy and right nephropexy at the same sitting when a movable kidney requires anchoring. He opens the peritoneum to the outer side of the ascending colon and follows the longitudinal bundles downward to the cecum where they join at the root of the appendix. The latter is delivered into the lumbar wound, and either inverted entire or else amputated and the stump treated by inversion without ligation. He has failed only four times in the fifty-six cases in which he has attempted lumbar appendicectomy, either from inability to find the appendix or to deliver it far enough into the wound. In these cases he supplemented the nephropexy by abdominal appendicectomy. The conviction is also gaining ground that there exists an intimate association between movable right kidney on the one hand, and cholecystitis, cholelithiasis and their sequelæ on the other. In a recent series of four nephropexies, for example, he found gallstones in two and chronic cholecystitis in the others. He therefore regards direct exploration of the appendix, gall-bladder and gall-ducts through the lumbar incision as one of the most important steps of the intervention. He has sometimes deliberately opened the peritoneum when not required for appendicectomy, for the sole purpose of making this exploration, but in certain cases he has been able to palpate the gall-bladder, gall ducts and under surface of the liver through the peritoneum without entering. His experience now includes 261 nephropexies done in 193 operations on 186 patients. All but three were women. The mortality in 846 nephropexies on record is between 1.5 and 2 per cent. His mortality was 1.55 per cent. in 193 operations. He used ether, alone or preceded by nitrous oxid, in all but four of the nephropexies. One of the latter patients was operated on under spinal cocaineization and painlessly, the intervention including at one sitting right nephropexy, lumbar appendicectomy, curettage of the uterus and inguinal shortening of the round ligaments. He keeps his patients on their backs for three weeks. Acute nephritis occurred in two patients, but was attributed to the ether by the physician in one instance, and recovery was complete in six and eight weeks. Slight albuminuria and blood cells were noted in ten cases—no more than occasionally follow mere palpation of the kidney. After the latter is delivered through the incision which is carried from rib to ilium along the outer border of the erector spinæ, the whole of the fatty capsule is removed, and the kidney is then returned temporarily to its place, while the

other abdominal viscera are explored and operated on as required, after which the peritoneum is sutured. The kidney is then delivered again. The process is facilitated by moving the patient up or down on the air bolster which is placed under the abdomen. The capsule proper is then incised on the convex border and detached to a line midway between the external and internal borders of the kidney. The loose portion is then turned back like the lapel of a coat over the still attached half. Four fixation sutures are passed through both, just below and parallel with the line of junction and the long axis of the kidney, each suture enclosing 2 to 3 cm. of the capsule. The kidney is then replaced and the sutures are brought out perpendicularly through the rear wall of the abdomen. The denuded kidney is thus brought against the denuded quadratus in apposition throughout the entire length of the latter, from rib to ilium. The article is illustrated with eleven fine cuts.

**90. Ligation of Abdominal Aorta for Aneurysm.**—Morris reports the 14th case in which the abdominal aorta has been ligated. All the patients have died, but in the four cases done since antiseptic methods have prevailed, Keen's patient lived for forty-eight and Tillaux's for twenty-nine days, while Milton's died the day after operation, from anemia and shock, and death occurred in this latest case from septicemia the third day. Morris ligated the artery temporarily with a soft rubber catheter held by long clamp forceps. The patient was a colored woman, 24 years of age, with a history of aortic disease dating back four months, accompanied by much epigastric pain and vomiting. The ligature was applied about two inches below the aneurysm, one and one-half above the bifurcation of the aorta. The operation could be done in fifteen minutes, but required thirty in this case. Nine hours after operation the balance between the vital signs was restored and the patient's legs became warm. Numbness and pain in the legs required morphin. Twenty-two hours after the ligation the pulsation in the aneurysm suddenly began to diminish, and the aorta decreased so rapidly in size that in about three hours the aneurysm had apparently disappeared and the ligature was removed—twenty-seven hours after it had been applied. The pulse became rapid and irregular at first, but soon subsided to 60 with the beat regular. The pulsation in both femorals showed that circulation in the extremities was restored, with sensation and sphincter control. Patient was quiet and comfortable, but symptoms of septicemia developed and were rapidly fatal. The portions of the bowel which had lain in contact with the steel forceps had gangrened, with resulting infection of a serous collection in the vicinity. The patient was in no condition to resist it on account of weakness from lack of nourishment and ulcerative gummatous nodules found in left kidney. The case demonstrates that an aneurysm of the aorta can be made to fill with clots in this way, and that circulation may be re-established by removal of the ligature. The evidence tends to prove that the operation may be successfully accomplished in the near future. Morris appends the summaries of the thirteen other cases on record.

**100. Hemochromatic Bodies in Pernicious Anemia.**—Incited by the statement of Adami, in *THE JOURNAL* of Dec. 23, 1899, that the condition of hemochromatosis is doubtless of bacterial origin, Yeakel investigated the tissues from several cases of pernicious anemia and has found just what was described by Adami, "irregular clumps of stumpy ovoids," minute "diplococci," some of the isolated ones showing "a fine halo about them." These pigmented bodies are not all diplococci; some seem merely to be fragmental particles. In the other cases the same hemorrhoidal bodies were found in the tissues, the liver, pancreas, spleen and to some extent the kidneys. He made cultures from the different organs of the body, as he states in the discussion following, in two of the cases, and found almost pure cultures of colon bacilli. This bears out fully Adami's view that the colon bacilli is the cause of this condition in pernicious anemia, though Yeakel does not consider it alone conclusive.

**102. Ovarian Pain.**—Hall maintains that what is called ovarian pain is largely due to the uterus and that in many cases where the ovaries have been removed the pain experi-

enced is reflex or sympathetic from inflamed endometrium and stenosed cervix.

**103. Astragalus Dislocation.**—Jepson reports a case in which the astragalus was not only in part comminuted, but rotated on its lateral axis, so that the surface for articulation with the tibio-fibular arch pointed toward the os calcis, and the fractured end pointed toward the tendo Achillis. Nevertheless, with considerable trouble and the severing of a number of tendons, thus running the risk of affecting the vitality of the bone, the dislocation was reduced and good results obtained. He summarizes as follows: 1. My own experience and the results of recorded cases lead me to believe that it will rarely be possible with our present knowledge and technique to bring about a reduction of a backward dislocation of the astragalus without opening the joint and bringing about a reposition of the bone by direct manipulation. 2. With our present command of aseptic surgery, I see no reason why this should not be undertaken in all cases uncomplicated by severe infection, with good prospects of securing a nearly perfect result. 3. Removal of the astragalus should be reserved for cases where the bone is completely separated from its ligamentous attachments, consequently having no adequate source of blood supply. 4. Amputation should be resorted to only in cases where the dislocation is compound and infected to a degree impossible of removal, and the patient's life jeopardized by the septic intoxication or infection.

**109. Ventrosuspension of the Uterus.**—Cousins performs an operation which he thinks is new to the profession or not yet described and which is briefly as follows: "An incision is made in the median line just above the symphysis, about an inch and a half long, or of sufficient length to admit two fingers, that the uterus may be brought up into the wound for inspection, and at the same time any adhesions present may be broken up. After having gotten the uterus and its adnexa freed and perfectly movable, I dissect away from the skin and the subcutaneous fat down to the fascia of the rectus muscle, pushing it back from the edge of the incision for about an inch and a half. I then take a sharp pair of forceps and introduce them about an inch and a quarter from the edge of the median incision, on a line with the lower angle of the abdominal incision. The forceps are then pushed through the fascia muscle and the peritoneum into the abdominal cavity. The next step of the operation is to grasp the round ligament about an inch and a half away from its uterine attachments and draw it up through the punctured wound made by the forceps through and above the external fascia of the rectus muscle. It is sutured there with catgut sutures. This procedure is repeated on the opposite side and the abdominal wound is closed with through-and-through silkworm gut sutures and a running catgut suture for the fascia of the rectus muscle." The uterus thus suspended has a space between it and the abdominal peritoneum. The outer extremity of the round ligament is put on a stretch which thus lifts the broad ligament forward and upward and suspends the ovaries. It has certain advantages, he thinks, over the Kelly operation, and though he has performed it only three times the results have been always good. It is less inconvenient to the patient, as she is allowed to be up in fourteen days and leave the hospital in two and one-half weeks.

**120. Formaldehyd.**—Howard finds formaldehyd inhalations almost a specific in scarlet fever and measles. He places a generating lamp in the room. If the gas causes irritation to the eyes and throat a little aromatic spirits of ammonia will control it, and sometimes increase the action. The room should be thoroughly ventilated several times a day and the gas regulated to suit the feelings of the patient, though they may require sometimes more than the healthy person would consider comfortable. He would also fumigate other children in the family for an hour morning and evening for a few days to prevent other cases. He also advises the inhalation use of formaldehyd in tuberculous cases. The formula which he uses is given as follows:

|                        |         |      |
|------------------------|---------|------|
| R. Formalin.....       | 3ii     | 7/50 |
| Chloroform .....       | 3i      | 3/75 |
| Alcohol .....          | 3iss    | 45   |
| Oil rose geranium..... | gtt. xx | 1/25 |

This is used from a light glass inhaler or a large mouth vial, in his tuberculous cases. In debilitated patients he uses small doses of strychnia. If the bladder becomes irritated by too large or long continued doses, suspension for a time with strychnia and the use of diuretics relieves the condition.

**133. Treatment of Diphtheria.**—The treatment of diphtheria recommended by Patterson consists in the use of muriatic acid with potassium chlorate according to the following formula:

|                             |      |       |
|-----------------------------|------|-------|
| R. Potassium chlorate ..... | 3i   | 3 75  |
| Dilute muriatic acid.....   | 3iii | 7 50  |
| Muriated tinct. iron .....  | 3iii | 11 25 |
| Distilled water .....       | 3xii | 360   |

The details of treatment are significant. As soon as the patient is seen, do not delay for the action of a cathartic or other medicine, but combat it at once by the administration of two tablespoonfuls every hour for adults, and proportionately less for children, of the above mixture. Administer it once or twice at night, with tonic doses of quinin thrice daily. He advocates mopping of the throat with a mixture of extract of pinus canadensis and phrenic acid, 10 to 15 drops, repeating it after each dose, and taking care not to wound the tender membrane. He reports that with this treatment, suggested by Dr. E. S. Gaillard, he has had remarkable success.

2. Quinin Bihydrobromate in Malaria.—Ferguson has met with a number of cases in which quinin taken by the mouth seemed inefficient, and he has experimented with various salts

of quinin for hypodermic use and finally hit upon bihydrobromate or acid hydrobromate of quinin, which dissolves readily in six parts of pure water. It is a perfectly stable salt, more reliable, he thinks, than any other, and probably more un irritating. He uses it usually by injecting 3 gr. of the drug dissolved in 20 minims of pure warm water under the skin of the upper arm, thigh, abdomen, or elsewhere, on alternate days. He keeps a syringe solely for this purpose, disinfects the syringe and the patient's skin with a strong carbolic lotion and carefully disinfects his own hands, besides carefully sterilizing the needle in the flame. He thinks it well to boil the solution every time it is used. With these precautions, he considers there need be no fear of tetanus even in the tropics. He thinks that very few or no patients with malaria can resist six doses of 3 gr. each of quinin bihydrobromate. Some of his patients have been cured in three doses; none of them required more than six injections.

3. The Boiling of Milk.—Ransom maintains the importance of boiling milk or sterilizing it for infant food. He says there is no sound evidence to show that milk raised to the boiling point, that is 110 C., or 233 F., or to a temperature of boiling water for ten minutes or a quarter of an hour, suffers any diminution of its nutritive qualities. Neither is it probable that if consumed within twenty-four hours after heating that it will cause infantile scurvy. The same is true of Pasteurized milk heated to 80 or 85 C. None of these methods render the milk absolutely sterile, but they do kill most pathogenic microbes such as those of tuberculosis, cholera, diphtheria and typhoid, and if the milk be drunk within twelve hours of heating, few or no spores will have developed. Pasteurization, he thinks, is less effective than boiling. In times of epidemic summer diarrhea the heating should be prolonged for at least half an hour and the milk drunk within a few hours, or subjected again to the process as the spores of the bacillus sporogenes enteritidis are very resistant. Under all circumstances milk, raw or sterilized, should be drunk as fresh as possible to diminish the liability to nutritional diseases. But it is his belief that infants who live wholly or mainly on milk, as at present supplied, should never be exposed to the dangers lurking in the raw milk.

4. Human and Bovine Tuberculosis.—After reviewing the evidences Cattle concludes that we can not as yet deny the possibility of infection by milk, but enough has been said, he thinks, to show that the assumption that the frequency of tuberculosis in early life is chiefly due to tuberculous milk is in one direction too narrow, and in another erroneous. The exclusive milk theory will cause us to ignore the greater incidence of tuberculosis on the lungs than on the bowels of young children, and it fails also to take account of the other sources of infection. There is no doubt that certain infantile diseases like measles, whooping cough, bronchitis, bronchopneumonia, etc., are powerful predisposing causes to tuberculosis mortality. They leave behind them constitutional weakness, respiratory catarrh, and often intestinal catarrh as well, and the widely disseminated bacilli of human tuberculosis gain a footing, attaching themselves to the most suitable organs, in the majority of cases the lungs and their related glands; in other cases to the intestines, ear or neck glands. Milk may be responsible for some cases, but the fact that thoracic tuberculosis is so common at an early age suggests the conclusion that human bacilli, inhaled or swallowed, mixed with the bodily secretions or with food, is the cause of chest trouble in one case and abdominal in another. The bulk of evidence tends to show that milk is not highly infective when diluted with the milk of healthy cows, and that some persons show a much higher degree of susceptibility than others.

6. The Open-Air Treatment of Consumption.—Wise brings forward evidence to show that the open-air treatment of consumption was carried out by Bodington in England in 1835, in spite of much opposition and with great success. He claims for him the origin of this method.

8. Forced Feeding in Tuberculosis.—In the conclusion of their report the committee summarize as follows: "1. That

since very large diet gave worse results than those of more moderate amount, the indiscriminate stuffing of all tuberculous patients should be replaced by systematic dieting. The diets as regards amounts and constitution should be determined in each case after due consideration has been given to the respective conditions as regards: *a*, the activity and extent of disease; *b*, amount below weight; *c*, digestive capability; and *d*, to some extent, personal dietetic likes and dislikes. 2. That in view of the bad effects which overfeeding gave rise to in the normal individuals, great care should be taken in the selection of a diet for patients who, as the result of treatment, have reached or passed their highest known weights. When this regain of weight is associated with arrested disease, the original diet found suitable for a person very considerably underweight and with active lesions, should be reconstructed more upon the lines of what would be suitable for the same person in perfect health. The observations were not sufficiently extended to allow of conclusions being drawn as to which diets gave the best results as regards the condition of the lungs; but subsequent sanatorium experience of two of us with the advantage of being able to carefully observe the course of pulmonary lesions in patients upon weighted diets, leads us to think that the lungs do not improve any more rapidly upon forced feeding than upon generous diets. Further, there is no doubt that anorexia, dyspeptic symptoms, and vomiting are much more frequently met with when working with very large diets than when more moderate amounts of food are given." They append tables of the diet and metabolism, which are of interest.

**9. Tumors.**—The third lecture by White considers the causation of tumors, the conditions of stable and unstable equilibrium, extrinsic and intrinsic causes, etc. He sums up his conclusions in the following: "1. Tumors are to be classified on a histological basis. The best mode of effecting this is to make use of the threefold basis of cells, tissues, and organs. 2. The rudiment from which a tumor springs may consist (*a*) of the structures normally present at the point of origin; (*b*) of an embryonic collection of cells such as is described by Cohnheim; or (*c*) of tissues of new formation, the result either of an inflammatory condition or of previous tumor formation. 3. Extrinsic factors play a part in tumor causation, but are not the determining factors—that is, the occurrence or non-occurrence of a tumor does not depend on extrinsic factors. In particular, the parasite theory is shown not to stand a critical investigation. 4. The determining factor in tumor causation is to be found in the intrinsic factors. 5. This determining factor consists in the existence of a condition of unstable equilibrium between the intercellular forces, so that proliferation once started is progressive and is not limited by the resistance of the surrounding tissues. 6. The causes of this instability are many and various and may be either intrinsic or extrinsic. 7. Proliferation having started, the cells acquire the habit of growth—that is, the power of independent proliferation which enables them to proliferate in parts of the body in which the condition of equilibrium is stable. 8. Tumors grow by the proliferation of their own cells. 9. Tumors do not invariably continue to increase without limit. Under certain circumstances they may cease to grow, and may diminish in size or even disappear completely. 10. Tumor formation is not to be regarded as an isolated process but is to be considered as one of a group of progressive processes with which it is closely allied. Still less must one form of tumor, such as carcinoma, be considered apart from the others." White remarks in regard to the treatment, suggesting that the removal of the extrinsic factors such as irritation, etc., should be attended to, and makes a further suggestion based on the excessive glycogen secretion of malignant tumors. The origin of this substance in tumors has not been investigated so fully, but probably the same two sources, carbohydrates and proteids of the body, are available as in diabetes. An examination of the quantity of nitrogen excreted in the urine should be of assistance in determining this point, but he has not learned of any systematic investigation in this direction. The urine in malignant disease has not received the attention that it deserves. The presence of wasting and

cachexia would seem to show that the proteids of the body are broken up, and it is very likely that glycogen arises, in part at least, from the destruction of proteid matter. If this is true we can not expect much from the carbohydrate-free diet since the body proteids would still remain as a source of glycogen. It is well known that malignant disease is very rarely met with in association with diabetes, and we know also that in acute diabetes wounds heal with great difficulty. The explanation of this is probably that the glycogen which is necessary for the proliferation of the cell is continuously being removed from the body as glucose. It is permissible, then to think that by setting up an artificial glycosuria we could remove the glycogen as fast as it is formed and so prevent it being available for supplying the energy necessary for the proliferation of the tumor. Such glycosuria may be set up by giving certain drugs such as phloridzin. This is a point worthy of investigation by therapeutists, but White does not expect much from such a treatment, because the drug would remove the glycogen from the normal tissues as well as from the abnormal, and it would be of little use to hinder the progress of a tumor if the surrounding tissues could not take advantage of the occasion by reacting and absorbing it. Much depends, therefore, on the question whether the abnormal or normal tissues would yield up their glycogen more readily. To facilitate the possibility of malignant disease progressing to spontaneous cure, as sometimes has been observed, measures should be taken which will raise the enfeebled resistance of the body; thus arsenic, which has a tonic action, has been found to be of some benefit. Coley's fluid probably acts in the same way, though Butlin finds that the benefit from it is only temporary. Hygienic treatment, of course, should be regarded. In conclusion, he would urge that the investigation of the pathology of malignant disease should not be left too much to bacteriologists. There is a great field for work in the study of clinical characters of malignant disease such as temperature, urine and cachexia phenomena. There is too much tendency at the present to regard micro-organisms as everything in the cause of disease and to neglect the personal or intrinsic factors.

**10. Smallpox.**—Thresh uses the prevalence of smallpox in a small hamlet opposite the smallpox hulks in the Thames river as evidence of the air-borne theory of smallpox. There has been no communication of late years between the ships and the community, and yet the disease occurs. He thinks it possible that the infection may be carried by the air two or three miles. Of course, there is the possibility of infected sewage into the river from ships, but there is no proof of it. He thinks, however, this sewage should be treated in some way before being allowed to flow into the Thames.

**12. The Danger of Celluloid.**—Burns from celluloid are not uncommon. Ogston has collected a number of cases which he briefly reports. He has investigated the subject experimentally to see what the effect of various degrees of heat have on celluloid articles and the especial point of ignition. Celluloid is capable of being ignited at a very low temperature when exposed to radiating heat and surrounded by substances of varying conductivity. He sums up his results in the following conclusions: "1. It is evident that celluloid articles of uncertain composition and dangerously explosive quality are everywhere sold and are in constant use, and that conditions in which they may ignite in varying circumstances can not be fully inferred from experiments regarding their ignition point made in a physical laboratory. 2. Badly manufactured celluloid ignites at variable temperature, too low for it to be safely used. 3. It also follows, I consider, that restrictions should be imposed upon the sale of all such articles which do not sustain, without ignition, a temperature equal to that sustained by well-manufactured celluloid. 4. It is worthy of consideration whether all celluloid articles of personal wear and such others as might give rise to fires ought not to be compelled to have the word "ignitable" conspicuously imprinted upon them. 5. If the suggestion of the writer in *The Lancet* to render celluloid incombustible by the addition of some chemical should be practicable it would be the best solution of the difficulty, and such

an addition ought to be made compulsory by legislative enactment."

**17. Hemorrhagic Pancreatitis in Malaria.**—Ross and Daniels report a case in which a man died with acute symptoms which did not indicate a malarial source, but the postmortem showed hemorrhagic pancreatitis, together with extensive necrotic and other changes in the stomach and intestines, with a great accumulation of the malarial parasites in the pancreas and in the capillaries of the stomach and intestines; very few were found in the spleen, liver and kidneys. There was also bacterial infection of the stomach and intestines to a large extent. The malarial parasites probably had remained latent and had increased rapidly in the intestines and pancreas, until finally they produced sufficient damage to the mucosa to allow other micro-organisms present to invade it. Pain was not a noticeable symptom at any time during the disease.

**20. Study of the Trypanosoma of Tsetse Fly Disease.**—Laveran and Mesnil ascribe to the trypanosomata, the *surra* of India, the *dourine* of Hungary, Spain and Africa, the *mal de cadere* of certain portions of South America and possibly also of the United States, and the tsetse fly disease. The measures which have proved effective against one will probably prevent the others.

**21. Study of Cattle Plague. Filtration of Virus.**—Nicolle and Adil-Bey have become convinced by their studies on the invisible germ of cattle plague—which passes readily through a thin Berkefeld filter—that it lives inside the leucocytes. They relate certain peculiarities, which are only to be explained by this assumption, which may aid in the study of other unknown parasites.

**23. Special Role of Carbohydrates in Utilization of Insoluble Salts in the Organism.**—Vaudin's tests demonstrated that the saliva alone, without admixture of gastric juice, is able to form maltose and dissolve a certain proportion of the insoluble salts. About 300 gm. of salted bread were chewed by some young people and ejected into a vessel and mixed with water. In two hours maltose had been formed in the proportion of 73.15 gm. to the liter, and .98 gm. of the insoluble salts was dissolved in the fluid.

**26. Chloroform Anesthesia in Heart Disease.**—Huchard maintains that accidents from chloroform anesthesia are no more frequent in persons with lesions of the heart or aorta than in cases of other affections. A cardiac or aortic affection is, therefore, no contra-indication to chloroform under the following conditions, namely: 1, that it is not in the acute stage of an infectious process; 2, that the organ affected is not too much degenerated; 3, that it is not in the astyolic or dyspneic stage nor exhibits symptoms of adhesion of the pericardium. In case of cardiac or aortic disease, the chloroform should be administered in small, progressive and continuous doses until the lid reflex is diminished. The entire suppression of this reflex is too close to the sudden dilatation of the pupil, which is often the precursor of respiratory or cardiac syncope. Chloroform well made and well administered does not kill, Sédillot used to say, and the maxim still holds good.

**27. Potato in the Treatment of Diabetes Mellitus.**—Mossé's further experience has confirmed his previous assertions—mentioned in THE JOURNAL of January 11, p. 137—in regard to the great value of potatoes as a substitute for bread in diabetes and its complications. Ingestion of 2.2 to 3.3 lb. of potato for several successive days will usually reduce the thirst and the amount of sugar in the urine, while there is a general improvement in the different elements which make up the urologic syndrome, as well as in the general health. This effect has been attained in 23 out of 24 cases in which 2.5 to 3 times as much potato as bread formed the daily diet. The potatoes can be cooked in any way, but when baked and with butter they are usually relished most. During the spring and early summer they can be incorporated in the bread. This makes a more appetizing bread than the usual substitutes for wheat flour. Mossé attributes the effect of the potato régime to the alkalies they contain in a vitalized form. The urine

loses much of its acidity and the general effect seems to be similar to that of a course of alkaline waters.

**30. Expectant Treatment During Period of Dilatation in Deformed Pelves.**—Pinard distinguishes between a primipara with a normal cervix and a multipara whose cervix is infiltrated with cicatricial tissue, in determining the proper procedure and the limits of expectant treatment. He applies the term *bassin limite* to a pelvis which has not permitted the normal accommodation of the pelvis during the pregnancy, but which may sometimes allow the passage of the fetal head.

**31. Vesicular Mole with Severe Vomiting.**—Pinatelle states that in one case the mole developed without symptoms until uncontrollable vomiting suddenly set in, requiring therapeutic abortion at the third month. In the other case there was a history of recurring metrorrhagia with cessation of fetal pulse and growth the fourth month, followed by grave vomiting. The case took a favorable turn and patient recovered. The abdomen ceased to increase in size, but débris of placenta and fragments of a mole were expelled at term. No fetus was found. Vesicular mole was accompanied by uncontrollable vomiting in 15 per cent. of the cases on record.

**39. Treatment of Surgical Tuberculosis by the High Frequency Current.**—Imbert reports three cases treated by this form of electricity with marked benefit in all, and one completely cured. The rapid and progressive improvement of the functional symptoms was most remarkable. One patient had a tubercular arthro-synovitis of the right wrist. He was a waiter, aged 34, and was able to resume work in two months. Forty sances, ten minutes each, with a current of 400 to 500 milliamperes, were given in the course of five months. The second case was a tubercular adenopathy of the neck, and the third, a tubercular diaphysitis of the right arm. The favorable results justify the application of this treatment to muscular atrophy consecutive to tubercular bone and joint lesions in general.

**40. Primary Cutaneous Actinomycosis of the Face.**—Pourpre has collected 10 cases of this form of actinomycosis in which the parasite was found. All the subjects recovered except one whose lung became involved.

**41. Cure of Leg Ulcer by Nerve Stretching and Vein Resection.**—Thévenot recommends this procedure as the operation of election for ulcers which are kept up by nerve or vein lesions, irrespective of the primal origin of the ulcer. In the case described, he stretched the external popliteal sciatic nerve, made a partial resection of the external saphena, and curetted the ulcer, resulting in the cure of an absolutely rebellious, recurring traumatic ulcer on the right leg, with neuralgic features.

**42. Resection of the Internal Pudic Nerve.**—Tavel finds but one case in which this operation was performed for vaginismus and is surprised that it has not more often been put into use. After giving the description furnished by Professor Strasser of the anatomic conditions, he reports two cases in which the operation was done for vaginismus and pruritus with success. He makes his incision midway between the tuberosity of the ischium and the anus parallel with the median line of the body, and bisected midway by the intra-ischiatic line. The incision is made to extend through the skin and the subcutaneous fatty tissue at the right, outside and behind the internal face of the ischium, to avoid injuring the inferior hemorrhoidal nerve. Following the fascia which covers the internal obturator, we will feel the pudic artery beating under the finger. It is not generally necessary to follow the nerve to the small sciatic notch, the branches which are to be resected are collected around the artery. The internal fascia of Alcock's canal once open, the nerves are isolated from the artery and accompanying veins. The motor branches are determined by slight irritation with a blunt instrument and observing the contraction. Those fibers which do not cause muscular contraction are sensory and their distribution is easily determined. Tavel advises resection simply of the labial, vestibular, or superficial perineal branches according to the extent of hyperesthesia and in some

cases it may be well to take also the clitoridian nerve. Post-operative treatment does not include drainage. In his cases recovery occurred without the least reaction.

**43. Gastrostomy.**—Terrier and Gosset describe their method of performing gastrostomy. It consists in vertical and left lateral laparotomy, dividing the fibers of the left rectus and drawing out the cone of the gastric coats, making three planes of sutures: a double plane which unites the sero-muscular coat to the posterior and anterior sheaths of the rectus and a superficial plane to unite the mucosa to the skin. The opening into the stomach is as small as possible so as to form a mucous cushion as an obturator which will plug up the opening. The muscle coats after the resection and the two parts of the rectus muscle play the part of a sphincter.

**44. Cicatricial Stenosis of the Pylorus.**—In this concluding chapter of their article Quenu and Petit describe the treatment at length. They find in reviewing the published cases that dilatation of the pylorus was performed in three cases, with one death and two failures. The operation is not satisfactory. Resection of the pylorus had four good results in four cases. Pyloroplasty gave a mortality of 21.7 per cent., five deaths in 23 operations. Gastro-enterostomy gave 5 successes in 7 operations, or a mortality of 28.8 per cent. It will appear from a superficial view of these results that pyloric resection was the operation of choice, but the cases are too few. Three of the patients operated on by pyloroplasty died of pulmonary tuberculosis, 5, 6 and 8 months after the operation. At the autopsy it was found that the pylorus was of normal diameter in these cases. The patient operated on by Bardeleben, on the other hand, remained cured for two years after the operation. Of the other cases we have little information except that three patients had some gastric trouble after the operation. One of these had a return of the vomiting and committed suicide. The autopsy showed an ulceration of the small curvature of the stomach. Of the five patients cured by gastro-enterostomy, four had been under observation for five or six months, but there has been apparent complete recovery and absence of any gastric phenomena. Hartmann's patient died of tuberculosis two years and a half after his operation, without the least stomach disorder. From the facts the authors are inclined to give the preference to gastro-enterostomy as the operation for stenosis of the pylorus following cicatricial contraction from caustics, etc., as giving less chances of relapse or ulceration. In a small number of cases gastro-enterostomy may be contraindicated, as when the stomach has been contracted to a mere channel between the esophagus and pylorus. In such a patient, Hartmann performed a duodenostomy. Such operation may be required if to the pyloric contraction is added a cardiac stenosis, but it is probable that the predominance of esophageal symptoms will lead the surgeon to first make a gastrostomy. Then, if it is impossible to feed the patient because the stomach rejects its contents, indicating a stenosis of the pylorus, gastro-enterostomy may be performed.

**45. The Clinical Use of Cytology, Cryoscopy and Hematolysis in Certain Surgical Serous Effusions.**—Juillard has investigated the utility of cytologic examinations for clinical purposes in articular and serosal effusions and hernial sacs. He finds that a cytologic study has a certain clinical value, but we must take account of the clinical pictures, the secondary irritations and the external application of medicinal appliances. It often happens that two effusions of the same origin have a different cytologic formula according as the occurrence of their evolution and their degree of acuteness varies. The existence of a general infectious disease and local lesions may exercise an influence on the cellular contents of the effusion. The intensity of the different stages of the morbid processes appears to be characterized in order from the slighter to the more severe by the presence in the effusion of, 1, endothelial cells; 2, lymphocytes; 3, polynuclear cells. The presence of eosinophiles is of no special importance, but they are met in diseases of infectious origin. The following conditions are characterized by the cellular contents consisting exclusively or mainly of endothelial cells or by the absence of any figured

elements: effusions of slow evolution; effusions of purely mechanical origin, as simple syphilitic chronic hydrocele; hydrocele symptomatic of slow syphilitic lesions of the testicle; mechanical hydrocele in case of generalized perineal edema; of tubercular arthritis of slow evolution; mechanical hydrarthroses; traumatic hemarthrosis and prerotulian hygroma, and certain effusions in the hernial sac of recent date. The following are characterized by cellular contents composed exclusively or mainly of lymphocytes: the infectious effusions, subacute or chronic; certain traumatic effusions; tubercular hydrocele; hydrocele following moderate trauma; chronic hydrohematocoele; encysted hydrocele of the cord associated with general infectious disease; certain recent effusions of the hernial sac; tubercular arthritis; tubercular synovitis with riziform granules; relapsing hydrarthroses; chronic traumatic hydrarthrosis and gonorrheal hydrarthrosis without fever. Polynuclear predominance characterizes acute effusions; chronic effusions in acute exacerbations; chronic effusions affected by severe traumatism; acute gonorrheal hydrocele; hernial effusions of many days' duration; acute rheumatic arthritis; certain prepatellar hygromas; chronic effusions which have been punctured, and old tubercular arthritides. Sometimes transition forms can be observed between any of these types. Effused contents in the sac of strangulated hernia contain endothelial cells and lymphocytes in recent cases, polynuclear cells in cases of several days' duration and where the intestinal lesions are advanced. Cryoscopy does not seem to give any very useful indications for diagnosis and hematolysis. The examination of the hemolytic power of effusions of the vaginal serosa is not of practical value. In hernial sac effusions it shows the presence of lysins which seem to increase as the morbid phenomena progress. As regard intra-articular effusions there may be hemolysins where the case is clearly infectious, and especially when it is acute. In cases of traumatic hemarthrosis and of hemorrhagic prepatellar hygroma, the hemolytic power of the effused liquids is in inverse ratio to the time between the examination and the beginning of the morbid symptoms.

**48. Treatment of Whooping Cough by Formol.**—Lamallerée has a pastille of paraform evaporated over an alcohol lamp every two hours in the room, which the child is not allowed to leave. In 20 cases treated in this way, the vomiting and paroxysms ceased in twenty-four to seventy-two hours in all but 2 of the children. In the others the cure was complete in eight days, with no treatment after the first seventy-two hours.

**50. Phlebitis in the Course of the Secondary Manifestations of Syphilis.**—Oettinger points out the superficial localization and multiplicity, the absence of embolism or any serious complications and the recovery under specific treatment, as distinguishing phlebitis occurring in the secondary stage of syphilis. It is very rare in comparison to the specific arterial lesions. The first symptoms soon subside, but a long interval elapses before the vein resumes its normal elasticity. Recurrence has been observed in several cases.

**54. Recent Publications on Prophylaxis and Treatment of Puerperal Sepsis.**—Bass reviews the literary output on this subject in 1897, 1898 and 1899, a total of 397 articles and monographs. In regard to serum treatment, he observes that the indispensable requisite for successful treatment with anti-streptococcus serum is the presence of streptococci, and it should not be given until they have been found. No evil results seem to have attended its use. Only 5 cases of exanthem are mentioned in a total of 134 cases treated with the serum. Credé's colloid silver treatment has also proved harmless and the results reported encourage a trial in severe cases. Courtney and Zoy are the only writers who recommend nuclein acid. Both claim that excellent results follow its use, on account of the hyperleucocytosis which it induces. The cases treated by extirpation of the infected uterus are not conclusive as to the benefits of the procedure. When the infection has spread beyond the uterus, it is ineffectual to arrest its ravages, and when it is restricted to the organ, the patient might have recovered without the operation.

**56. Treatment of Peritonitis Due to Spontaneous Rupture of Gall Bladder Containing Stones.**—König opposes the idea that a normal gall-bladder can burst from pressure of accumulated stones. In the cases on record the walls have always been found thickened and enlarged at some points and shrunken, thin and easily torn at others, with decubitus in many instances. Cholecystectomy is the simplest and most rapid method of treatment and the results he describes in a recent case, a woman of 70, confirmed its advantages. If the rupture occurs without preceding acute and severe inflammation in the gall-bladder, the infection of the peritoneum is mild. The perforation of a decubitus lets a few non-virulent bacteria into the peritoneum, and the resulting peritonitis is at first slight and very slowly progressive. If the abdominal cavity is cleaned and the gall-bladder removed, the peritoneum will take care of the small amount of infected bile left in it. But on the other hand, when the peritonitis has progressed into a severe form, or a preceding attack of gallstone colic suggests virulent infection, the abdominal wound should be left open after the extirpation of the gall-bladder. Perforation of the gall-bladder is accompanied by symptoms indicating rupture of a viscus. The symptoms of peritonitis do not appear until later. Tenderness is most pronounced at the points where the gallstones rest on the serosa and add a mechanical factor to the irritation and induce a tendency to vomit. Diagnosis is difficult in the cases which have never exhibited any preceding symptoms of the lithiasis, as in the one he describes. An important aid in differentiating is the subsidence of the vomiting when the patient reclines quietly, while the peritonitic symptoms persist. In his and Hochenegg's case, the diagnosis was obscured by a distended loop of intestine adherent at the point where the tenderness was most marked, merely a coincidence in each case.

**57. Death Under Chloroform from Paralysis of the Heart.**—Laqueur adds another to the 12 cases of sudden death under chloroform from paralysis of the heart which Kundrat collected in 1895. Heusler witnessed a similar fatality under ether. Nordmann has collected 4 cases of the sudden death of robust young persons during a cold bath, and the sudden death of a Berlin colleague's child after a single preventive injection of antidiphtheria serum probably belongs in the same category, as also Pott's case of sudden death of a child on the introduction of the tongue spatula. All the subjects were apparently healthy children or young persons, but all had one feature in common, a very large, persisting thymus, with actual hyperplasia in some. The spleen and tonsils were also unusually large in most of the cases. Enlargement of the follicles at the base of the tongue is constant in such persons.

**58. Infection and Auto-Infection.**—Wassermann reviews the results of recent researches in regard to the protecting powers of the organism against infection. The bactericidal action of fresh normal serum is due to its two constituents, the between-body and the complement, and when one or the other is deficient, the bactericidal power diminishes. Ehrlich has recently demonstrated that after excluding the liver in animals by intoxicating them with phosphorus, certain complements vanish from the serum. He has thus established that chronic affections of internal organs are liable to deprive the organism of these important protecting substances. Metchnikoff has also recently demonstrated that the complements vanish in the course of chronic suppuration. Von Dungern's observation has shown that certain cells in the organism are able to bind these complements and annul their action. He found that dead tissue possessed this property to a notable degree. These findings suggest an explanation for the readiness with which patients under similar conditions yield to infection. It has likewise been established lately that the protecting and curing substances which are elaborated in the course of certain self-limited infections are formed in the bone marrow, and that the germs causing the infection, or their products, have to reach the bone marrow before the protecting substances can be elaborated. This has been most thoroughly studied in typhoid fever. The germs which find their way into the bone marrow

may linger there for years after recovery, their proliferation checked by the natural protecting powers of the serum. But if the normal circulation is interrupted by any cause, traumatic or otherwise, and the serum loses some of its protecting power, then the germs commence to proliferate and inflammatory processes are liable to develop in the marrow or periosteum. The passage of isolated germs into the blood and thus into the bone marrow, occurs more frequently than generally supposed, and is probably the essential factor in the elaboration of the protecting substances in the marrow.

**60. Renal Colic, Renal Hemorrhage and Nephritis.**—Senator does not agree with Israel in his assertions that renal colic can be caused by congestive tension or inflammation of the kidney except in rare cases. Neither is hematuria to be ascribed to this cause. Consequently, incising the kidney is not the proper method of treating renal colic or renal hemorrhage. The colic is caused by adhesions between the kidney and neighboring parts, and the resulting displacements of the organ are probably the cause of the hemorrhage. Talma pointed out some years ago that slight displacements of the kidney which cause no disturbance in healthy persons, induce nervous renal colic in persons with hypersensitive abdominal ganglia. Senator bases his statements on Israel's own cases, pointing out that in his 14 patients there was no congestion nor tension in 11, and yet the patients were cured after the intervention—incision of the kidney—in all probability from the detaching of adhesions. Even when a focus of inflammation is discovered in the kidney it is not necessarily the source of the colic and bleeding, which are the effect of other causes, except in cases of complete anuria by retention, painfully distending the organ. Israel's 14 cases include a number with pyelitis, gonorrhea, cystitis and movable kidney, suggesting the certainty of adhesions, while other writers have expressly noticed the presence of adhesions in their cases.

**61. Tetanus Germs in Gelatin.**—Levy and Bruns dissolved 2 to 3 gm. of ordinary commercial gelatin in 100 c.c. of bouillon and kept it for eight to ten days at 99 F. They then inoculated mice with .3 to .4 c.c. of the filtrate. All of the animals developed typical, fatal tetanus in two or three days. Inoculation of .2 c.c. caused a chronic tetanus of the hind leg nearest the point of the injection. Guinea-pigs also succumbed in two to four days after inoculation with 2 to 5 c.c. of the filtrate. These results were obtained constantly with four out of the six specimens of gelatin used in the tests. Further research showed that exposure to steam for eight minutes was not sufficient to sterilize the gelatin in all the tests. The results indicated that different tetanus germs have a varying susceptibility to high temperatures. The problem is still undecided as to which element in the gelatin is responsible for the hemostatic action, and whether this element would be injured by a temperature sufficiently high to actually destroy all the tetanus germs. Research in this line is needed.

**62. Clinical Utilization of Agglutination of Tubercle Bacilli.**—Rumpf has been testing the exact condition of the resisting powers of the organism in the struggle with tuberculosis, by means of the agglutinating reaction. Koch believes that the agglutinating property and the protective substances in the body parallel each other, and that the former is therefore the index of the latter. In his communication translated in *THE JOURNAL* of December 21, p. 1710, he states that it is possible to promote the elaboration of the protective substances by repeated injections of tubercle bacilli dust, and that the progress accomplished can be estimated by the agglutinating reaction. Rumpf found the test positive in 84 per cent. of 107 patients in various stages of tuberculosis, in 17 patients with a one-fifth dilution and in 73 with a one-tenth or still weaker dilution. He made comparative tests with Arloing's and with Koch's method of agglutinating and found the results parallel in many cases. The agglutinating reaction was marked, even without artificial stimulation, during the first period of the patients' stay in the sanatorium, showing the general benefit derived. Six patients who had been injected with old tuberculin three

times for diagnostic purposes, showed marked agglutinating power and 5 others were treated according to Koch's directions with repeated injections of the bacillus emulsion or "new tuberculin." The agglutinating property was very much enhanced in all of them and in one it reached the strength of 1 to 100, even after only three injections of comparatively small doses (.0025, .005 and .01). These were all patients in the second or third stages, in which it is more difficult to obtain the reaction. The interval is still too short to determine the permanent benefit derived from this application of Koch's method. No harm nor ill effects of any kind were noticed. The details of the agglutinating reaction in the 107 cases are tabulated.

**67. Simple Method of Preserving Specimens for Microscopic Clinical Diagnosis.**—Rohnstein states that this method has been in use at Senator's clinic for three years, and has given constant satisfaction. The specimens must be in a natural condition, neither stained nor dried. All fluid is strained out of feces, sputum or matters derived from the stomach, and the solid matters left are mixed with the preserving fluid, which is a mixture of 20 parts formol and 125 of glycerin in 200 of distilled water. If urine is to be examined, it is set aside to settle, and the fluid is siphoned off the sediment. It is then mixed with a corresponding amount of water and set aside for another twelve to twenty-four hours to settle again. This fluid is again siphoned off, and the same quantity of the preserving fluid is added. By this means all the albumin in the urine is removed in the supernatant fluid. A few crystals of thymol are added to the urine to prevent cloudiness from bacterial action. The material can be kept in this preserving fluid for years without losing its natural appearance. Specimens that have been thus preserved for three years are not altered and are ready for microscopic examination at any time, just as when fresh.

**73. Treatment of Nocturnal Enuresis and Pollutions.**—Porosz is convinced that both are due to defective development or deficient function of the prostate, unless a central origin is unmistakably apparent. He consequently treats them by Faradization of the prostate through the rectum and reports excellent results.

**74. Hypophrenic Pains and Neuroses of the Celiac Plexus.**—Hoffman ascribes certain subdiaphragmatic pains to a neurosis of the celiac plexus. They are characterized by their location in the upper portion of the abdomen, whence they radiate into the lower portion, but not to the genitalia nor into the legs. They also radiate backward into the sacral and gluteal regions, but not upward. When these pains are accompanied by scybala and polyuria, the combination forms a syndrome which justifies the assumption of a neurosis of the celiac plexus.

**75. New Test of Lungs for Forensic Cases.**—Placzek notes that the pressure in the cavity containing the lungs is zero in the fetus, while after air has once entered the lungs it is never entirely evacuated, and the manometer shows negative pressure. It is therefore possible to determine with the manometer whether an infant was born alive or not, by the amount of negative pressure in the lung cavity. The floating test and the eye will supplement the findings of the manometer and determine whether respiration was partial or complete.

**79. Dietetic Treatment of Stomach and Intestinal Affections.**—Among the points emphasized by Schmidt are the necessity that food entering a diseased intestine should be in minute particles and should make the least possible demands on its chemical digestive functions. He advises reducing the tendency of milk to putrefy by the addition of salicylic acid in the proportion of .25 to .5 gm. to the liter. This precaution has proved very effectual in his experience in treating gastric and intestinal affections. This successful attempt to disinfect the food suggests that other experiments in the same line might give fine results. An antiseptic diet seems to be particularly advisable in case of achylia, but the same result may sometimes be accomplished by administering hydrochloric acid.

**80. Statistical Study of the Consequences of Lues.**—Matthés has undertaken to record the morbidity of the syphilitics whom he has had occasion to treat since 1875. He intends to report on them every five years. He states that tabes occurred in about 1 per cent. of 698 certain cases of lues, and paralysis in 1.1 per cent. The mortality is higher than the average; most of the deaths occurred from intercurrent tuberculosis. His experience disproves the generally accepted belief that syphilis acquired late in life has an unusually severe course. About 75 per cent. of the survivors have living children, but in 35.6 per cent. births had been preceded by abortions and the death of nurslings.

**83. Study of Eclampsia Cases.**—Braitenberg states that he has had occasion to observe 46 cases of eclampsia in the last fourteen years, a proportion of 5.47 per cent. of the total number of births. Only 12 cases occurred in parturients who arrived at the clinic after labor had commenced. The others were all in persons who had been for some time in the institution, the maximum eight weeks. These cases in the clinic occurred sometimes in groups, once coinciding with an epidemic of influenza. The 6 cases in multiparæ were all extremely mild, with merely a single eclamptic attack, except in one case of carbolic poisoning. Nearly 33 per cent. of the patients had an abnormally small pelvis. Albuminuria was pronounced in all but 4 of the patients. The eclampsia developed during the pregnancy in 4, with an average of 10 attacks, and 25 per cent. mortality; during delivery in 24 per cent., with an average of 3.5 attacks and mortality of 12.5 per cent.; during the puerperium in 18, with only 2.1 attacks and no mortality. In the 18 cases in which delivery was artificially accomplished there were no further attacks in 50 per cent. In 2 of the fatal cases, marked cerebral apoplexy was found at the autopsy, so pronounced in one case that it may have been the primary affection and might have developed without the pregnancy, on the basis of old endocarditis and atheromatosis. In one case the fetus was extracted by Cesarean section immediately after death. The heart beat had not been perceptible six hours before and the fetus was in extreme rigor mortis.

**86. Brown-Sequard Injections in Treatment of Atrophy of Optic Disc.**—Castresana has been making a systematic test of this method of treating both gray and white atrophy. Vision was not restored to normal in any case, but all were much improved. One patient could count fingers at half a meter after twenty injections and at one meter after twenty more. The improvement subsided after the injections were suspended, and he proposes to resume them every two or three months in order to maintain the benefit derived.

**88. Tolerance of Strychnin.**—Alvarez prescribed spartein sulphate in a daily dose of 4 eg. for a patient with ataxia cardiaca. The druggist gave her strychnin sulphate, and the patient took 2 eg. morning and night. Instead of causing contractions, the strychnin induced an actual ataxia. The languor was so extreme that she could neither walk nor stand without support for four to six hours after each dose. The tetanizing effect was restricted to a severe and painful trismus. The symptoms subsided after suspension of the drug.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. A Practical Exposition of the Methods, Other Than Drug-giving, Useful in the Prevention of Disease and in the Treatment of the Sick.** Edited by Solomon Solis Cohen, A.M., M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic. In Eleven Octavo Volumes. American, English, German and French Authors. Volume VI, Dietotherapy and Food in Health. By Nathan S. Davis, Jr., A.M., M.D., Professor of the Principles and Practice of Medicine in Northwestern University Medical School. Cloth. Pp. 372. Price, for the set complete, \$27.50 net. P. Blakiston's Son & Co. 1901.

**RECHERCHES CLINIQUES ET THERAPEUTIQUES SUR L'EPILEPSIE, L'HYSTERIE, ET L'IDIOTIE.** Compte-rendu du Service des Enfants

Idlots, Epileptiques et Arriérés de Bicêtre l'année 1900. Par Bourneville avec en collaboration de MM. Crouzon, Dionis de Séjour, Izard, Laurens, Paul-Boncour, Philippe et Oberthur. Volume XXI. Avec 19 figures dans le texte et XI planches. Paris: Progrès Médical. 1901.

THE ACCESSORY SINUSES OF THE NOSE, Their Surgical Anatomy and the Diagnosis and Treatment of Their Inflammatory Affections. By A. Logan Turner, M.D. (Edin.), F.R.C.S. Ed., Surgeon for Diseases of the Ear and Throat, Deaconess Hospital, Edinburgh. With 40 Plates and 81 Figures. Cloth. Pp. 211. Price, \$4.00. New York: Longmans, Green & Co. 1902.

A POCKET CYCLOPEDIA OF MEDICINE AND SURGERY. Based upon "A Cyclopaedia of Practical Medicine and Surgery." Edited by George M. Gould, A.M., M.D., Editor of American Medicine, and Walter L. Pyle, A.M., M.D., Assistant Surgeon Wills Eye Hospital, Philadelphia. Leather. Price, \$1.00. Philadelphia: P. Blakiston's Son & Co. 1902.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA. The State Board of Health Organized 1847—Session 1897. Selma, April 20-23, 1897. Cloth. Pp. 450. Montgomery, Ala.: Brown Printing Co. 1897.

TRANSACTIONS OF THE AMERICAN ORTHOPEDIC ASSOCIATION. Fifteenth Session, held at Niagara Falls, June 11, 12 and 13, 1901. Volume XIV. Cloth. Pp. 369. Philadelphia: Published by the Association. 1901.

ON DISORDERS OF ASSIMILATION, DIGESTION, ETC. By Sir Lauder Brunton, M.D., D.Sc., LL.D. (Edin. and Aberd.), F.R.S., F.R.C.P. Cloth. Pp. 495. Price, \$4.00. London and New York: Macmillan & Co., Ltd. 1901.

VALID OBJECTIONS TO SO-CALLED CHRISTIAN SCIENCE. By Rev. Andrew F. Underhill, Rector of St. John's Church, Yonkers, N. Y. Paper. Pp. 49. New York: Edwin S. Gorham. 1902.

ANIMAL EXPERIMENTATION. A Series of Statements Indicating Its Value to Biological and Medical Science. Paper. Pp. 177. Price, \$1.00. Boston: Little, Brown & Co. 1902.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. By George Henry Fox, A.M., M.D. Part VIII. Price, \$1.50 each. Philadelphia and London: J. B. Lippincott Co. 1901.

THE KEW COWL TESTS. Preface by Perry Fairfax Nursey, C.E., Post President of the Society of Engineers. Paper. Pp. 43. London: Hickson, Ward & Co. 1902.

ELEVENTH ANNUAL REPORT OF THE STATE BOARD OF MEDICAL EXAMINERS of New Jersey, 1901. Paper. Pp. 46. Trenton, N. J.: MacCrellish & Quigley. 1902.

MENTAL GROWTH AND CONTROL. By Nathan Oppenheim, M.D. Cloth. Pp. 295. Price, \$1.00. New York: The Macmillan Co. 1902.

CONTRIBUTIONS FROM THE WILLIAM PEPPEL LABORATORY OF CLINICAL MEDICINE. (Reprints.) No. 2. Paper. Philadelphia. 1901.

REPORT OF THE KENSINGTON HOSPITAL FOR WOMEN. From Oct. 8, 1900, to Oct. 14, 1901. Paper. Pp. 29.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 20 to 26, 1902, inclusive:

Edward B. Bailey, contract surgeon, now at Demopolis, Ala., to the Division of the Philippines, via San Francisco, Cal.

E. B. Barnett, contract surgeon, leave of absence extended one month, on the expiration of which he will report to the chief surgeon, Department of Cuba, for annulment of contract.

Joseph T. Clarke, captain and asst.-surgeon, U. S. A., leave of absence for twenty days granted.

William H. Corbuser, major and surgeon, U. S. A., member of a board at Governor's Island, N. Y., for the examination of officers for promotion.

Oscar F. Davis, contract surgeon, now at Bloomington, Ind., to duty at Fort DeSoto, Fla.

Mills Dennis, contract surgeon, now at Temple, Tex., to the Division of the Philippines, via San Francisco, Cal.

Robert C. Eve, contract surgeon, former orders amended to relieve him from duty at Fort Sam Houston, Tex., and to proceed to his home at Augusta, Ga., for annulment of contract.

Edward T. Gibson, contract surgeon, from Fort Harrison, Mont., to San Francisco, Cal., for duty as transport surgeon on the transport *Meade*.

Frank D. Pease, contract surgeon, from Fort Mackenzie, Wyo., to duty at Fort Harrison, Mont.

Elias H. Porter, contract surgeon, former orders so amended as to direct him to proceed to San Francisco, Cal., from Fort Hancock, N. J., instead of from Louisa, Ky.

Milton Vaughan, captain and asst.-surgeon, Vols., leave of absence for two months granted.

Clarence A. Warwick, contract surgeon, now at Keokuk, Iowa, to the Division of the Philippines, via San Francisco, Cal.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ending March 1, 1902:

Medical Inspector D. N. Bertolette, detached from the *Brooklyn* and ordered to the *New York*.

Surgeon G. T. Hibbert, detached from the Cavite Naval Station and ordered to the *Brooklyn*.

Surgeon J. E. Gardner, detached from the *New York* and ordered to the Naval Hospital, Cavite, P. I.

Asst.-Surgeon J. J. Snyder, ordered to Port Royal Naval Station for temporary duty with recruiting party.

Asst.-Surgeon B. L. Wright, when discharged from treatment at Naval Hospital, New York, ordered home and granted sick leave for three months.

Surgeon L. W. Sprattling, ordered to Buffalo, N. Y., for duty at the Naval and Marine Recruiting Rendezvous.

Surgeon H. L. Law, retired, detached from duty at the Naval and Marine Recruiting Rendezvous, Buffalo, N. Y., and ordered home.

Asst.-Surgeon W. H. Ulish, reported at the Naval Hospital, Mare Island, Cal.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Feb. 27, 1902:

Surgeon T. B. Perry, granted leave of absence for seven days from Feb. 12, 1902.

P. A. Surgeon A. R. Thomas, relieved from duty at Glasgow, Scotland, and directed to proceed to London, England, for duty in the office of the U. S. Consul-General.

Senior Pharmacist, A. M. Roehrig, granted leave of absence for six days from Feb. 5, 1902.

Junior Pharmacist Frank Siedenburgh, granted leave of absence for three days from Feb. 19, 1902.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 28, 1902:

#### SMALLPOX—UNITED STATES.

Alabama: Birmingham, Jan. 1-31, 5 cases.

Alaska: Uooniah, Jan. 29, 8 cases.

California: Sacramento, Feb. 8-15, 1 case; San Francisco, Feb. 9-16, 20 cases.

Colorado: Denver, Feb. 8-15, 5 cases.

Illinois: Feb. 15-22, Belleville, 2 cases; Chicago, 5 cases; Dan-

ville, 7 cases; Galesburg, 2 cases.

Indiana: Elkhart, Feb. 1-15, 20 cases; Evansville, Feb. 15-22, 14

cases; Indianapolis, Feb. 8-15, 8 cases.

Iowa: Clinton, Feb. 15-23, 1 case.

Kentucky: Covington, Feb. 16-23, 6 cases.

Louisiana: New Orleans, Feb. 15-22, 2 cases.

Maine: Feb. 15, Durham, 5 cases; Freeport, 1 case; Portland,

2 cases.

Maryland: Baltimore, Feb. 15-22, 3 cases.

Massachusetts: Boston, Feb. 15-22, 19 cases, 4 deaths; Cam-

bridge, Feb. 15-22, 4 cases; Everett, Feb. 14-21, 1 case; New Bed-

ford, Feb. 14-21, 3 cases; Newburyport, Feb. 15-22, 1 case; Quincy,

Feb. 15-22, 2 cases; Waltham, Feb. 15-22, 1 case.

Michigan: Feb. 15-22, Detroit, 5 cases; Ludington, 7 cases.

Minnesota: Minneapolis, Feb. 8-22, 48 cases.

Montana: Butte, Feb. 9-16, 4 cases.

Nebraska: Omaha, Feb. 15-22, 45 cases.

New Hampshire: Nashua, Feb. 15-22, 1 case.

New Jersey: Feb. 15-22, Camden, 3 cases; Jersey City, 23 cases;

Newark, 29 cases, 5 deaths.

New York: Binghamton, Feb. 15-22, 2 cases; New York, Feb. 15-

22, 55 cases, 13 deaths; Yonkers, Feb. 14-21, 1 case.

Ohio: Cincinnati, Feb. 14-21, 19 cases; Hamilton, Feb. 15-22, 1

case; Middletown, Feb. 8-15, 1 case; Youngstown, Feb. 8-15, 1 case.

Pennsylvania: Allegheny, Feb. 15-22, 2 cases; Lebanon, Feb. 15-

22, 1 death; Philadelphia, Feb. 15-22, 63 cases, 15 deaths; Pitts-

burg, Feb. 15-22, 1 case; Reading, Feb. 17-24, 1 case; Steelton,

Feb. 15-22, 1 case.

South Carolina: Charleston, Feb. 15-22, 4 cases.

Tennessee: Memphis, Feb. 15-22, 6 cases.

Texas: Fort Worth, Jan. 1-31, 8 cases; Houston, Feb. 15-22, 12

cases.

Vermont: Burlington, Feb. 15-22, 17 cases.

Washington: Spokane, Feb. 8-15, 25 cases; Tacoma, Feb. 8-16,

8 cases.

Wisconsin: Green Bay, Feb. 16-23, 9 cases; Milwaukee, Feb.

16-22, 2 cases.

#### SMALLPOX—FOREIGN.

Austria: Prague, Jan. 25-Feb. 8, 12 cases.

Belgium: Antwerp, Jan. 25-Feb. 8, 16 cases, 3 deaths.

Brazil: Bahia, Jan. 10-25, 2 cases, 1 death.

Canada: Halifax, Feb. 15-22, 1 case; Victoria, Jan. 4-11, 1 case.

Colombia: Cartagena, Feb. 3-9, 2 deaths; Panama, Feb. 10-17,

50 cases, 10 deaths.

France: Nantes, Jan. 1-31, 2 cases; Paris, Feb. 1-8, 3 deaths.

Great Britain: Birmingham, Feb. 1-8, 1 case; Glasgow, Feb.

7-14, 6 cases, 1 death; Liverpool, Feb. 1-15, 26 cases; London,

Feb. 1-8, 1102 cases, 82 deaths; Plymouth, Feb. 8-15, 1 case, 1

death.

India: Bombay, Jan. 14-28, 9 deaths; Karachi, Jan. 12-19, 10

cases, 3 deaths; Madras, Jan. 17-24, 2 deaths.

Italy: Naples, Feb. 1-8, 11 cases; Palermo, Jan. 25-Feb. 1, 1

death.

Malta: Feb. 1-8, 2 cases.

Russia: Moscow, Jan. 18-Feb. 1, 32 cases, 12 deaths; Odessa,

Jan. 25-Feb. 8, 11 cases, 3 deaths; St. Petersburg, Jan. 25-Feb. 1,

13 cases, 4 deaths.

Straits Settlements: Singapore, Jan. 4-11, 1 case.

Uruguay: Montevideo, Jan. 4-11, 65 cases, 6 deaths.

#### YELLOW FEVER.

Mexico: Vera Cruz, Feb. 8-15, 2 cases, 2 deaths.

#### CHOLERA.

India: Bombay, Jan. 14-20, 7 deaths; Madras, Jan. 11-24, 3

deaths.

Straits Settlements: Singapore, Dec. 28-Jan. 11, 4 deaths.

#### PLAGUE.

India: Bombay, Jan. 14-28, 643 deaths; Karachi, Jan. 12-19, 26

cases, 25 deaths.

### THE PROSTATE.

JOHN B. MURPHY, A.M., M.D.

Professor of Surgery, Northwestern University, Chicago Post-Graduate School and Hospital, and Chicago Clinical School.  
CHICAGO.

In the very recent literature the surgery of the prostate has been given a much deserved prominence. The patient and long suffering of those with prostatic trouble is unnecessary to mention as an incentive to active investigation in this particular field. We believe that the recent procedures have been sufficiently tried to justify their regular performance, and that they give us reasonable assurance of safety to the patient and permanency of relief. It appears to us that it is now a matter of improvement of technic in the operations and a dissemination among the general profession of the importance of the early performance of operative procedures that is most needed. Before citing cases the author takes the liberty of considering the anatomy and physiology of the prostate, as well as the etiology and pathology of prostatic hypertrophy.

#### ANATOMY.

The prostate is a glandular and muscular body situated in front of the bladder, entirely behind the triangular ligament or deep perineal fascia—See Fig. 1 from Toldt—immediately anterior to and in close contact with the rectum, and completely surrounds the prostatic urethra. It is tunneled by the prostatic urethra, the urethra occupying the second anterior fifth of the space, from before backward.

Five-sixths of the bulk of the normal prostate is behind the posterior level of the urethra—See Figs. 2 and 3. Its greatest fixation is by its attachment to the posterior layer of the triangular ligament. When the ligament is divided therefore, and the prostate freed from it, it permits of considerable latitude of motion. On the anterior surface it is rather loosely attached to the urethra; on the posterior surface it is firmly fixed to the urethra; the mucous lining of its glands and of the ejaculatory ducts and prostatic sinuses are continuations of the mucosa of the urethra—See Fig. 4—so that it is not possible to remove the entire prostate without removing the prostatic portion of the urethra at the verumontanum—See Fig. 2 from Toldt. It is possible to remove the lateral and posterior lobes of a hypertrophied prostate, allowing its isthmus to remain, and retain the anterior portion of the urethra and three-fourths of its circumference—See Fig. 5 from Toldt. The anterior urethra is crescent-shaped, its convexity forward; the posterior surface of the urethra vaults forward into this

crescent, the elevation being made up of the caliculus, utriculus, ductus ejaculatorii and the connective tissue surrounding them—See Fig. 5—and the middle lobe behind as shown in Fig. 6.

The middle lobe, in the normal anatomical condition, is a small, bullet-shaped, tongue-like projection from the base of the prostate, posterior to the urethra. It is not a lobe, when compared with the lateral lobes; it is merely a projection in the direction of the bladder from the posterior commissure, between the lateral lobes; and when the lateral lobes and posterior commissure are removed, it is practically detached except from the mucosa, as shown in Case 7.

The gland is surrounded by a distinct capsule—Fig. 5—which is smooth over the lateral lobes, but is depressed into the gland and divided into layers around the vessels in the median line. This vascular area runs parallel with the urethra and directly in the center line. Capsular divisions, therefore, in the removal of the gland should be made over the lateral lobes and parallel with the line of the urethra, that this vascular area may not be invaded until the lateral lobes are decapsulated and prepared for extirpation, and the hemorrhage thus avoided. The seminal vesicles recede from the prostate—See Figs. 3 and 4—along the posterior wall of the bladder and are closely attached to it.

The vesico-rectal peritoneum is a long distance from the base of the prostate, and in subcapsular enucleation its integrity is not in danger of being disturbed.

The arterial supply of the prostate is from the inferior vesical and middle hemorrhoidal arteries. These are subdivided at the inner margin of the capsule into small arterioles, and when the true capsule is peeled off they give rise to little hemorrhage. The veins which form a plexus in the capsule empty into the vesico-prostatic plexus.

The lymphatic supply is meager: the vessels accompany the venous plexus, and finally end in the internal iliac nodes. The nerves of the prostate are branches of the hypogastric plexus.

In its minute structure the organ is made up of a stroma of connective tissue, smooth muscular fibers and glandular tissue—See Fig. 5. The muscle fibers constitute about one-half of the entire mass of the gland—See Fig. 5—and are continuous with the muscle fibers of the bladder wall above; below they are mingled with a small amount of voluntary muscular tissue derived from the transverse perineal muscles.—(F. H. Gerish.)

The glands are of the branched or tubular variety. They secrete a milky fluid, which at the moment of ejaculation is added to the seminal fluid, and appears to play an important rôle in the motility of the sperma-

tozoa, as without the addition to this fluid, in some of the lower animals, fecundity can not take place.

While in its normal anatomical position the prostate stands in front of the bladder and surrounds the urethra—See Fig. 2—in its hypertrophied condition it has an entirely different relation to the bladder. It normally extends backward onto the bladder only to the sphincter vesicæ internus—See Fig. 7, which shows bladder wall with prostate removed. In its pathologic or hypertrophied condition it incapsulates the neck of the bladder in a cuff-like manner, extending many inches upward on its wall, and often protrudes into the vesical cavity, carrying on its surface the muscularis and mucosa vesicæ; occasionally a pedunculated lobe may be extended through the muscularis and only retain the mucous covering; this, however, rarely occurs except from the posterior lobe. In the normal anatomical condition, the muscular fibers of the prostate are continuous with the muscular fibers of the apex of the bladder wall, but as the prostate enlarges it extends cone-shaped and upward on and around the neck of the bladder, and its muscle fibers in the upper part appear to be distinctly

it is called 'sphincter vesicæ internus' (at point *a*, Fig. 7). Around the urethra just outside the bladder is a circular layer of striated muscle, which is frequently designated as the external sphincter, or sphincter urethræ."—Am. Text-Book Phys., 1896.

Figure 1 shows the relation of the prostate to the deep perineal fascia, the rectum, the bladder, the seminal vesicles and ureters.

separate, or at least easily separated from the muscle fibers of the bladder. This anatomic relation gives distinct assistance and guidance as to the best method of removal or separation of the prostate from the bladder wall, i. e., at the extreme apex of the bladder it would be difficult to distinguish between the prostatic and bladder muscular fibers, while, if the base of the prostate be exposed, the prostate can be shelled from the bladder wall, from above downward, with ease and with comparative safety to the integrity of the bladder wall, i. e., if we look upon the prostate as a cuff, closely attached at its apex to the bladder wall, and loosely attached at its base, we can see how its lateral lobes can be scrolled or rolled forward with ease, with the assistance of hook retractors, until it reaches the apex attachment, as shown in Fig. 8.

#### PHYSIOLOGY.

"At the cervix of the bladder the circular layer of muscular fibers is strengthened, and has been supposed to act as a sphincter, with regard to the urethral orifice;

Figure 2.

Figure 3.

Figures 2 and 3 show the relation of the prostate to the prostatic and membranous urethra, as well as the relations to the bladder wall and the seminal vesicles.

When the urine accumulates in the bladder, to prevent its escape the elasticity of the parts, aided by the

tonic contraction of the internal sphincter, suffice. This function of the circular layer of fibers, which composes the internal sphincter, is disputed by some observers. That this sphincter controls, absolutely, the flow of urine, I have demonstrated conclusively on three of my cases after the prostate was removed, and the posterior prostatic urethra entirely removed with it. It was necessary in these cases to introduce a forceps or a catheter to allow the urine to escape from the bladder when the operation was complete, showing that the sphincter vesicæ internus has complete control of the urine, without the aid of the sphincter urethræ, notwithstanding the statements of so many authorities to the contrary. "When the accumulation in the bladder becomes greater the external sphincter is brought into action."—Am. Text-Book Phys., 1896. This we have been unable to observe, as the extensive operation interferes with this sphincter. If the desire to urinate is strong, the external sphincter is undoubtedly controlled by voluntary effort, but whether or not in mature filling

circular layer continuous with the inner and middle layer of the bladder. There is also a sheet of striped muscle which surrounds the greater part of the urethra, and extends from the level of the entrance of the vasa deferentia into the urethra to within a couple of inches of the urinary meatus. In man, the first part of this muscle is represented by a few transverse fibers on the ventral surface of the lower half of the prostate gland, and is known here as the external sphincter of Henle. Around the membranous portion of the urethra the sheet is termed the constrictor urethræ, and around the penile portion, the accelerator urinæ."

"The mechanism of closure of the bladder has been the subject of much discussion. Retention of urine has been variously ascribed to the elastic resistance of the tissues at the neck of the bladder, or to the contraction of the internal sphincter, or to the external sphincter of Henle. Heidenhain and Colberg proved that the elasticity at the neck is not the only factor in closing the vesico-urethral orifice, as the bladder of the dead subject will not stand the same pressure as the living without leakage through the vesico-urethral orifice. If the lumbar spinal cord be disturbed, the condition in favor of the living animal is abolished, showing that it depends

Figure 4 shows the relation of the urethral mucosa to the ejaculatory duct and prostatic sinuses, and the relation of the prostatic substance to the prostatic urethra.

of the bladder it is brought into play by involuntary reflex, is not definitely determined. Emptying the bladder may be prevented, if desirable, when it is filled, by voluntary contraction of the sphincter urethræ. According to Goltz, the voluntary control of the process of micturition is limited to the action of the external sphincter and the abdominal muscles. The contraction of the bladder is purely an unconscious reflex, taking place through a lumbar center.

"Careful dissection fails<sup>1</sup> to show any thickening of muscle around the commencement of the urethra sufficient to constitute a sphincter; the absence of such a sphincter has been especially emphasized by Griffiths, and can be easily verified by dissection. There are, however, around the urethra, collections of unstriated and striated muscle, which by their contraction close this canal and check the urinary flow. Thus, the first part of the urethra is surrounded by a muscular coat, consisting of inner longitudinal fibers and an outer, thicker,

Figure 5 shows the horseshoe shape of the prostatic urethra. Also the elevation of the floor of the urethra into the crescentic anterior wall which covers four-fifths of the entire circumference of the urethra. The fibers of the prostate extend into the verum montanum.

on the existence of a tonic contraction, under the influence of this part of the cord. There is no doubt that the greater part of the resistance offered to the outflow of urine is occasioned at the vesico-urethral orifice, only a small part being offered by the urethra itself. Thus, in surgical operations, the urethra may be incised up to the neck of the bladder without the escape of urine; and in the cat the urethra between the neck of the bladder and the prostate gland may be divided completely without any of the urine escaping. Reyfisch has excised the prostate in dogs without producing incontinence. Experiments show that the resistance to the outflow of urine is situated at the neck of the bladder, and must be due either to the tonic contraction of the circular fibers at this point, or to the elastic retraction of this orifice, aided perhaps by the position of the mucous membrane along the whole length of the urethra." Great care must, therefore, be exercised in any operation on

the neck of the bladder, not to interfere with the zone of control in the act of micturition.

Not only is the sexual function diminished or lost by the removal of the prostate, but it is materially interfered with by prostatotomy, as in the Bottini operation. Guiteras<sup>2</sup> says: "The patients are not *always* incapacitated for sexual life by the Bottini operation." From our observation it would appear that the prostate

Figure 6 shows the tit-like projection of the middle lobe into the floor of the urethra.

gland is placed over the neck of the bladder as a secondary muscular development. Its greatest bulk is made up of muscular tissue. It has situated within it a small glandular structure; the urinary control is entirely independent of the prostate, as was shown in my cases; for, if the prostate was removed, the urine did not escape, except in cases where the bladder wall had been torn in liberating or detaching the enlarged prostatic lobe. It is rather an accessory to the sexual function

Figure 7 shows the muscle fibers of the bladder and the sphincter vesicae internus, (a) with the prostate removed.

than to the urinary apparatus. G. Buckston Browne<sup>3</sup> believes that the prostate has no especial urinary function, whatever. W. H. Howell<sup>4</sup> says: "By careful experiments upon white rats Steinach has shown that the removal of the seminal vesicles and prostate gland, while not diminishing the sexual passion and the ability to perform the sexual act, including the actual discharge of spermatozoa, prevents entirely the fertilization of the

ova. Removal of the seminal vesicles, alone, remarkably weakens the fertilizing power of the semen. The secretions of these accessory glands are essential to the mo-

Figure 8 shows the hook retractors as applied to the prostate.

bility of the spermatozoa, and they may have other important functions." The function of the prostate is to contribute the prostatic fluid to the semen; the specific use of this fluid is not known.

Figure 9 shows changes in the shape of urethra produced by the myomata. (Transverse section.)

#### ETIOLOGY.

Browne believes that we have no reliable data on which to base a theory of the prostatic enlargement. However, he says, when asked how to avoid the malady: "I would suggest plain living, exercise on foot, very moderate worship at the shrine of Venus after 50 years of age."

The age at which prostatic enlargement begins is variously estimated. L. Bolton Bangs<sup>5</sup> believes that it

begins a considerable time before the 50th year, and that the earliest manifestations of prostatic hypertrophy are not generally recognized. Prostatic hypertrophy is extremely rare in Japan, India and China,<sup>6</sup> while in Turkey it is of comparatively frequent occurrence.

Schultze<sup>7</sup> states that enlargement of the prostate is rarely found in the negro, although he describes one in which the middle lobe, obtained by autopsy, measured 5 by 7 centimeters, and microscopic examination showed a marked hyperplasia.

We do not believe that excessive sexual indulgence plays any more part in enlargement of the prostate than in the production of fibroma of the uterus; and it is well known that, proportionately, fibromata of the uterus

two, principally the combinations, and not infrequently there is a general hypertrophy of the entire gland without any distinct tumor formation, resembling closely the soft, flabby subinvolved uterus—See Fig. 12, Case 3. The enlargements are many times completely incapsulated, as shown in Figs. 18 and 19. Case 7. In a great majority, however, they are closely connected with the prostatic tissue itself—See Fig. 18, Case 7—just the same as in the intramural fibroid there is always an enlargement and hypertrophy of the uterine tissue associated with the myoma—See right lobe, Case 7, Fig. 18. In the lateral lobes the tumors are most frequently intramural, as seen in Fig. 19, Case 7, next submucous. In the middle lobe they are often pedunculated, rarely intramural and practically never subcapsular.

Wishard<sup>6</sup> draws particular attention to the mechanical character of the obstruction in hypertrophy of the prostate, and to the direction which the enlarged body takes,

Figure 10.

are more common in the unmarried than in married women. Then again, it is markedly absent in such races and nationalities as the Japanese, Chinese, Negro and Indian.

Our exact knowledge of the etiology of enlargement of the prostate may be summed up by saying that we know nothing definite about it.

#### PATHOLOGY.

The benign neoplasms and enlargements of the prostate resemble very closely in their histology, in their mode of development and in their relations to the organ itself, the non-malignant neoplasms of the uterus. First, they are myomata, fibromata and combinations of these

Figure 11.

Figures 10 and 11 show the traction hooks used for drawing down the prostate.

i. e., towards the bladder, in the direction of the urethra or in the direction of the rectum, as the case may be; the size in one direction bears no particular relation to its size in the opposite direction. It interferes more or less with the urinary function, depending upon the direction of the pressure whether it be upon the urethra, bladder or rectum.

#### MEDICAL TREATMENT.

James R. Hayden<sup>8</sup> strongly favors a conservative palliative treatment, and claims that while it does not cure, it at least prepares the patient better for the operation. His treatment consists of strict dieting, assisted by urotropin in full doses, to render the urine alkaline (sodium phosphate would accomplish this much better), and the administration of hyoscyamus, kava kava, tritium repens and uvi ursae, associated with daily rectal injections

of hot saline solutions and sitz baths. However, when operation is resorted to, he favors prostatectomy, either by suprapubic or perineal route.

The development of forceful and scientific procedures in the treatment of prostatic lesions has scarcely kept pace with the development of operative procedures in other fields of surgery. It has, however, though tardily, developed on the same lines with its analogous organ in the female, the uterus. Surgery of the prostate gland is now rapidly taking definite form on rational mechanic, anatomic and histologic bases.

Figure 12 shows the gland removed from Case 3. Natural size.

During the last quarter of the century the sufferer presented a lamentable picture. Usually a man of great energy, strong mentality, physically robust, indefatigable in his labors, and by these had gained a competence whereby he could spend his declining days in comfort prostate; by this he is deprived of his sleep, and the pursuit of pleasure were it not for his suffers intensely from pain, and sees no ray of hope for relief from his prostatic enlargement or its unpleasant sequences except in the grave. This picture may not fit the few, but it does fit the many, who suffer to a pathologic degree from prostatic enlargement.

Temporary catheterization is resorted to for the relief of urinary retention, which comes on after some undue exposure, acute illness, traumatism or what not, which produces a temporary retention. This should be accomplished with all aseptic precautions, with the greatest gentleness in mechanical manipulation; it can always be accomplished where there is an absence of stricture of the urethra anterior to the prostate. There is no such condition as prostatic stricture. The urethra is always patent in its prostatic portion, and the obstruction offered to the passage of the catheter is the obstruction due to deformity, pockets, prostatic sinuses and compression of the urethra by encroachments on its lumen from various directions by the enlargements or neoplasms in the prostate itself as shown in schematic drawing, Fig. 9. All of these occur on the posterior and lateral portions of the urethra; the anterior portion offers no obstruction. The ideal course of the catheter, therefore, is

along the anterior wall of the urethra. It is only a question of proper manipulation and an estimation of the directions of the canal for the successful accomplishment of temporary catheterization. In this, force must play no part. It should and can always be accomplished by those of skill and experience, in primary urinary retention, and the patient is, therefore, never forced to an immediate operation on his prostate under these circumstances, because he is then often in an unfavorable condition for operative procedure. The soft rubber, with or without the lead stilet, and the coudee

catheter, preferably of large size, are the best instruments to use. In these primary retentions the bladder may be completely emptied.

Continued or chronic retention presents to the surgeon many distinctly different, as well as dangerous, phases. Under these circumstances the bladder is often enormously enlarged; its veins are compressed, its walls anemic from pressure; its arteries are frequently dilated, and advanced pelvic or peripheral renal changes may have taken place. Because of this protracted compression of the combined urinary surfaces, care must be exercised that this pressure is not too suddenly relieved, i. e., that the bladder is not completely emptied; otherwise we have found by experience that there is an immediate congestion of the urinary surfaces, often followed by hemorrhage, frequently by shock, chills, fever and death. A chronic sufferer from vesical distension should never have his bladder completely emptied in a primary catheterization.

#### PROSTATOTOMY (BOTTINI).

Dr. Ramon Guiteras<sup>9</sup> may be said at present to favor prostatectomy, but he admits that a large portion of the cases are in such condition that no radical operation is justified; the Bottini operation in his hands has afforded this class of patients great relief. He has

Figure 13 shows photograph of prostate from Case 2, reduced one-half.

made a thorough investigation<sup>10</sup> of the Bottini method and comes to the following conclusions: "It is difficult to conceive why an operation consisting simply in burning linear scars into the sides and floor of the prostate gland and followed by the casting off of sloughs, should cause such a reduction of the urinary obstruction, and such a contraction of the gland; clinical evidence, however, supports the truth of this statement." Incontinence is rare after prostatectomy (Bottini). The cure of incontinence is not due to increased strength in the vesical sphincters, but to relief of the over-distended

bladder, as the pre-operative incontinence in the sufferer is due to over-distension rather than lack of sphincteric tone.

There can be no doubt there is an immediate relief of the urinary retention and its most distressing sequences by the Bottini operation in properly selected cases.

Dr. Hugh H. Young's experience with the Bottini operation covers 40 cases.<sup>11</sup> Six were lost sight of; 34 operations were performed on 31 patients, three patients having each two operations; the ages of these patients averaged very high, eighteen being over 67 years: of

that the symptoms immediately following the Bottini operation are, frequent urination, with considerable pain; hemorrhage, either primary or secondary (in about one-third of the cases); fever in 30 per cent. and chills in 20 per cent.; and that the post-operative period, in which these symptoms are present, continues for from two to three weeks. Incontinence, an annoying symptom, was present in 6 per cent.; 9 per cent. were operated on twice, and 2 per cent. of these were not benefited by the secondary operation; in 20 per cent. there was no benefit. Guiteras<sup>14</sup> collected 753 prostatotomies; 622 were cured (85.5 per cent.); 44 died (5.8 per cent.); 87 were failures (11.5 per cent.). Dr. J. W. S. Gouley<sup>5</sup> concludes that the Bottini operation has no advantages over the Mercier operation, which he introduced in this country in 1878, and has performed fifteen times. He believes that the operation of prostatectomy is the one indicated where the prostate is enlarged, whether soft or hard. Dr. S. Alexander<sup>5</sup> considers that the technique of the prostatectomy bearing his name is a most dangerous and difficult one, and he is disposed to discuss its failures rather than its successes. He considers the Bottini operation favorable in selected cases,

and wishes to impress upon its adherents that the obstruction in prostatic enlargement is not intra-vesical, and, therefore, could not be observed with the cystoscope or searcher. Willy Meyer<sup>5</sup> believes that the width as well as the depth of the incision in the Bottini operation is important. He uses permanent Mercier catheter after the operation, and keeps the urine loaded with antiseptics. He considers that prostatectomy is the more surgical procedure, and that the after-treatment is much less difficult and arduous than after the Bottini operation. He also considers the soft prostate difficult to cure by prostatectomy.

The destruction of the prostate was accomplished by

Figure 14 shows photograph of prostate from Case 4, reduced one-half.

fifteen over 70 years of age, all are alive and well; three of the 31 died, two of these four and five weeks after the operation, from uremia; one from sepsis from a periprostatic abscess due to a 4.5 centimeter incision puncturing the capsule. In all there was an immediate relief of the urinary retention. Of 20 cases which were operated on a sufficient length of time to admit of deductions as to the result, 17 were cured, two improved and one unimproved. Of the 8 others, the conditions were good up to the present time. All dispensed with the use of the catheter.

Dr. Bangs,<sup>12</sup> in commenting on his results with the Bottini operation, says 60 per cent. of the subjects threw

Figure 15 shows prostate from Case 5, natural size.

away the catheter; about 20 per cent. have an increased amount of spontaneous urination; and 20 per cent. received little or no benefit. He secures special advantages by the use of his solid tip metal catheter after the Bottini operation. In the 40 cases he reports, there were three deaths directly attributable to the operation. Two of these were from sepsis and one from shock. Notwithstanding these apparently favorable results,<sup>13</sup> he pronounces the operation a serious one, and not to be lightly undertaken; that the danger is in proportion to the severity and extent of the operative procedure:

me a few times at the Alexian Brothers' Hospital by means of thermo-cautery through the suprapubic route with a vaginal rubber speculum inserted into the bladder, but the average results were such as not to encourage me in continuing the work, and I have abandoned it for perineal prostatectomy.

(To be continued.)

Influenza is epidemic in various parts of Great Britain, the House of Commons furnishing center of infection.

## PROLONGED INTUBATION.\*

EDWIN ROSENTHAL, M.D.

PHILADELPHIA.

On the evening of May 23, 1888, I was one of several hundred who listened to Joseph O'Dwyer, in the Hall of the College of Physicians, Philadelphia, in a lecture before the Philadelphia County Medical Society. In the proceedings of the society I find the following note:

"Before reading his paper, Dr. O'Dwyer exhibited tubes with a metallic attachment to replace the epiglottis in swallowing, one of them being so arranged with a spring that the finger might be introduced behind it, as an extractor. In order to illustrate through how *small* a space [the italics are mine] breathing can occur, he exhibited a specimen from a case in which there had been no choking of voice or other sign of laryngeal involvement. Many fear that the tube will slip through the trachea. A tube was exhibited in situ in a 3-year-old larynx, showing that this accident can not occur if the proper size tube for the age be employed."

I quote so fully from the originator of this operation for it seemed to me that when O'Dwyer matured his matchless set of instruments he considered every condition that might arise, and thus in a measure gave a remedy.

The progress of intubation from an experimental procedure to an exact operation may be divided into three stages. 1. The introduction, where the master lectured to the student, exhibited his materials and asked for a trial. 2. In which the operation underwent the test of many investigators. Its merits and demerits were studied, the good retained, the bad dropped, and every part of the operation—from the instruments, tubes, gag, introducer, extractor, or even the silk necessary to be used—was carefully tested, and the final judgment appeared with the discovery of the serum treatment. This second period, which may be termed the transitory period, embraced the years intervening from the time that O'Dwyer presented his operation until its acceptance by the profession as an exact and independent operation, and ended when intubation, spoken of as a primary operation to tracheotomy, ceased to be considered. The third stage began with the advent of antitoxin and, as the operation was so thoroughly studied in the transition period, those familiar with the operation were ready to investigate those minute details which before had failed by reason of the generally fatal course of this type of the disease.

Before the serum period, intubation at its best was only an "expectant procedure," and the details of its technique was mostly an invention. We can show no greater example of the value of the serum treatment than to exhibit the statistical records of this operation. For, where before the serum period we described our results by the percentage of recoveries, we now record our results in the percentage of deaths. To the antitoxin is also due the very many discoveries made in the progress and sequelæ of diphtheria, and most conspicuously in the "laryngeal type," and especially those most serious cases requiring intubation.

We have thus been enabled to study more fully the value of this procedure, and we have found that we are not only liable to relieve the impending suffocation—the most urgent symptom—thus using it simply symp-

tomatically, but we have, as we progressively watched and studied our various cases, found that the operation of intubation has assumed a new standing for the relief of such cases; and where before we looked upon the operation simply as an expectant one we now place it among our certain remedial methods, most reliable, and of exact and certain promise. Indeed, so certain has an enlarged and accurate clinical experience impressed us, that what we before looked upon as an expectant method, the recovery being the exception, we now look upon as a specific method, a death being the exception.

Studying intubation, various authors have taken up the different difficulties formerly met. Some have studied the injuries resulting both in intubation, as well as extubation; others the methods. Various instruments and devices have been presented to expedite either the intubation or the extubation, with no injury to the patient. Some have attempted improvement either in the tubes, or the various instruments necessary to the operation.

But the most important and valuable work of the many investigators, to my mind, was the study of the technique of the operation. In other words, not so much the method of the operation, but its object, i. e., the study of the time required for the tube to do its work to cure the patient, and the time required for the tube to remain in the larynx in a simple or normal case of diphtheria of the larynx.

In this work I can claim some originality, and the result of my labors was presented to the J. Aitken Meigs Medical Association, in Philadelphia, as well as to the Medical Society of the State of Pennsylvania. I was not alone in this line of investigation, for Johann v. Bokay, Budapest, was doing the same work, and presented his results at the same time. These papers, printed in Europe, have been translated, and widely circulated and have given to others an incentive for the same methods of study. They have also resulted in a certain rule of practice and have given us an appreciation of what may be considered a normal case of intubation.

## RULES TO FOLLOW IN NORMAL CASES.

A collective study of the time consumed for a tube to do its work in patients cured of diphtheria of the larynx has shown us surprising results as an example of the influence of the antitoxin treatment. Before the antitoxin period it was an impossible question to say how long a tube should remain in the larynx. We had certain rules, given by O'Dwyer himself, and these briefly were as follows: An attempt to remove the tube from the larynx should be only after seven days, and even then we should always be ready for prompt reintubation should the case require it.

This rule was universally followed, and never questioned until the investigations of Bokay and others proved that the antitoxin had reduced this period, and a collective study has reduced the period to five days. So that this is now a very good rule in practice: in a normal case of laryngeal diphtheria make the first attempt at extubation after a period of five days, or, to be more exact, after 120 hours.

If, however, the case requires a reintubation at once, or even a week later, it may be assumed to be abnormal. It should come under the category of prolonged intubations, for then it will be impossible to prognosticate correctly the time when the tube may be left entirely from the larynx.

\* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

## THE TYPE OF THE DISEASE AS A FACTOR.

Before the antitoxin period it was my common practice to make a first attempt at extubation only after seven days; and a frequent reinsertion was almost always expected. Hence, I could never predict in any given case when I would finally remove the tube, or when the case was better. It was the rarest incident for a patient to be relieved in less than a week. This was done never by my hands, always in such instances by expectoration, when the relief of the stenosis proved that the tube was no longer required.

It was then a very common occurrence for me to see a tube worn two or three weeks, while a longer period than this was never considered by me to be anything extraordinary.

If, after the throat was clean and free from the specific bacilli, the patient was unable to exist without a tube, I would then consider the case one of prolonged intubation, and the case would linger for weeks, or perhaps months. Dr. William M. Welch, of the Philadelphia Municipal Hospital, records a case of three months. Finally, a cure or death, or the operation of tracheotomy would change the character of the case.

From this very brief and concise summary of what may be now termed ancient history of the pre-antitoxin period of the evolution of intubation, one can quickly conclude that the knowledge of the value and the practice of the method was in a truly chaotic and rather uncertain condition. With the specific character of the antitoxin, was opened a way to consider the causes that lead to prolonged intubation, and when such incidental cases appeared the opportunity was taken by all to investigate the reasons thereof.

## CAUSES OF PROLONGED INTUBATION.

First, I reject injuries as a cause. A careful and expert intubator must never, or should never record injuries as a reason. This can be left to the novice or to the clumsy or careless.

Injuries should be considered a specific study, and as they result always in a tracheotomy, should come under this category. Bokay, who has made special investigations, gives their treatment as tracheotomy; and as an injury, both in intubation or extubation needs very prompt treatment, I would not consider the treatment of the result, by intubation, of such injuries as a true case of prolonged intubation, even if the tube will be required a long period.

I would divide the causes of prolonged intubation into three, namely, 1, the type of the disease as a factor; 2, the result of the disease, or its sequel, as a factor, and 3, the result of the operation, the wearing of a tube as a factor.

*The Type of the Disease as a Factor.*—The natural cause of prolonged intubation in the disease may receive a specific name—chronic laryngeal diphtheria, or chronic croup. This as a cause for the prolonged presence of the tube in the larynx has very recently been noted. Before the Section on Laryngology, at Columbus, Ohio, I read a paper on this subject. In all my cases antitoxin was used, and hence they were treated specifically for the diphtheria. The croup persisted, even after the absence of the Klebs-Loeffler bacilli was proved bacteriologically.

The presence of the streptococci was considered as the cause, and the cases, being treated with the anti-streptococcal serum, were cured. In these cases, two in number, the duration of the intubation was into the

third week. My method of treatment will be related in concluding this paper. Investigating this particular subject since then, I found that others had made the same observation as to the disease. F. Egidi (*Due Casi di Crup Chronico*) divides this class of cases into three: First, those prolonged by tracheotomy; second, those prolonged by treatment without an operation, and third, those prolonged by intubation. Egidi, whose study of intubation before and after the antitoxin era is so well known, has even gone so far as to invent certain instruments essentially useful for such cases as these. At the second reunion of the Italian Society of Laryngologists, Rhinologists and Otolologists, he presented a paper (*Stenoses laryngees et leur traitement*) on laryngeal stenoses, and divided them into three categories: 1. Chronic stenoses (*les stenoses chroniques*). 2. Acute stenoses (*les stenoses aigues*). 3. Traumatic stenoses (*les stenoses ayant une cause externe*). He thus proved his familiarity with the varieties calling for accurate treatment and the need of the various instruments that he devised.

Those familiar with the treatment of croup by intubation have noted a primary as well as a secondary type: The first, where the disease begins in the larynx; the last, where it is a continuation of the disease from a nasal or faucial type. The latter may be taken as the type which may give rise to such cases as prolonged intubation. Where it exists with, and is a complication of, other types of diphtheria and requires intubation its history may be the same as any normal case. But when it comes after all the first symptoms have disappeared and can be classed as a reinfection, even if its appearance is a day or a week after the disappearance of the first symptoms, and even if these first symptoms were laryngeal and required intubation, the case belongs to that category of "chronic croup" requiring the same prompt treatment, the same reintubation and the same collateral treatment, but should then be classed as a case of prolonged intubation and with the abnormal cases.

*The Result of the Disease, or Its Sequelæ, as a Factor.*—By far the greatest or most frequent cause for prolonged intubation may be placed to the sequelæ of the disease. Paralysis of the vocal cords appear the most frequent. As Augustus Caillie ("The Modern Management of Diphtheria and Croup Cases") succinctly says: "Secondary stenosis after intubation due to abduction paralysis has been reported, but lacks confirmation." But so many cases have been recorded to which this cause has been given, cited by Engelmann, Fischer, Waxham and others, on this side of the Atlantic, and by Bokay, Trumpp, Egidi, Galatti, Massei, Escat and others in Europe, that its presence can be no longer a question. If the fact of the treatment, with recovery, of such a condition being the cause of chronic stenosis requiring the prolonged presence of the tube will be considered, I think I am right in speaking of this sequel as the most frequent.

With paralysis of the vocal cords being a sequel, and a cause for wearing of the tube, the other effects may be said to be the result rather of the paralysis than a pure and simple disease. However, the presence of the tube frequently gives rise to irritations. If, therefore, its presence be permitted to too great an extent this irritation results in other conditions which are of themselves abnormal.

*The Result of the Operation, the Wearing of the Tube, as a Factor.*—A familiar subject of intubation,

now so thoroughly investigated, is the injuries resulting from the presence of the tube. The irritation set up by the tube results in an inflammation, which in its turn results in edema or suppuration. Some authors claim that such results are chiefly due to traumatism—laceration produced by efforts in intubation or even extubation. Lacerations may be produced in the former by using too much force in an irregular attempt; in the latter, by missing the opening of the tube, by the lips of the extracting instrument, and dilating the blades and withdrawing, the larynx is injured. Waxham, in *Sajous' Annual and Cyclopedia of Medicine*, has so thoroughly described all these lesions that I can do no better than quote it.

"A number of causes have been enumerated as rendering necessary the long-continued use of the tube. Principal among them may be mentioned the formation of diphtheritic exudate or its long persistence in the larynx and trachea; edema of the tissues; ulceration of the cricoid cartilage and consequent collapse of the thyroid cartilage; cicatricial contractions and exuberant granulations following ulcerations and abduction paralysis. In some of these lesions, the lesion is due to a too tightly-fitting tube, to leaving the tube in too long, to poorly-constructed instruments, and some to injuries resulting from unskilful operations."

I can not say from personal experience that the injuries thus enumerated are very frequent. That they occur, or have been noted and recorded, is sufficient evidence for a constant prophylaxis.

The most frequent condition met with and one that the most painstaking efforts can not prevent is edema. This I have seen often enough. To speak more at length. Edema of the larynx results from various causes besides the presence of the tube. I have been frequently convinced that edema necessitating intubation in cases that were first benign, or requiring prolonged intubation, in cases intubated and pursuing a normal course, has resulted from the improper uses made of local remedies. For instance, using the strongest peroxid of hydrogen, either with a mop, or a syringe, or an atomizer. The irritation set up by the too copious use of this medicament, I am sure, has been the cause of more harm than good. I can speak thus plainly because I am so faithful in the use of this drug. I never intubate without first cleansing the mouth and throat, as well as my tube with it. But, where I formerly used peroxid of hydrogen of the greatest strength I could obtain, I now use it in the opposite way, as weak as I can. Again, where I employed it hourly in an atomizer to cleanse the tube, I now use it only when I intubate or extubate. Other medicaments may be as harmful, but not being so generally known and used have not received the prominence the peroxid has. The Germans are right when they record using the simplest local remedies, like boric acid, or the like. Since I have rejected the constant use of local measures (using them only when indicated, and then the weakest), cases of prolonged intubation or those requiring the tube have grown less.

To summarize briefly the instances that require the prolonged use of the tube, I would begin with chronic croup, paralysis, and edema. Our aim is to end the intubation as quickly as possible. If other conditions exist, besides these mentioned, the intubation should become a tracheotomy, for the longer the tube acts as an irritation, I fear, the worse the results.

#### REPORT OF CASES.

CASE 1.—A case before the antitoxin period. Mary S., aged

4 years, 10 months, living in the country. Patient of Dr. Anderson, of Paschalville. This child's home was isolated. The nearest neighbor was probably a quarter of a mile. This case was referred to me by Dr. Orville Horwitz. I dwell on the surroundings so that the method of treatment may be understood. The case was intubated with a No. 4 tube. I chose this rather large tube because the distance to my home was over 10 miles, and I did not wish that the child should expel the tube by coughing. On the eighth day I extubated in the usual way, but after an hour reintubated. After one week I again extubated, but had to intubate more promptly. The third time, the extubation and reintubation was performed as quickly as possible; not a moment was lost; the child did not breathe alone during the interval. The fourth and fifth extubation and reintubation were repetitions, and I began to think this child could not exist without the tube. Her general condition was good. During the interval of my visits the child was permitted to do much as she liked. It was the time when croup was considered one disease, and diphtheria another. On one of my visits I had to wait until the father went to the fields and brought the patient. This case taught me many things, and the one that I have adhered to: never to interfere too much with the peculiar idiosyncrasy of my patient. I permit them to fix themselves—after each intubation—in a way that gives most comfort. I have had as a result a fair average of recoveries, and never any in which dorsal decubitus results. This child was extubated and reintubated by myself seven times, when it occurred to me to use a smaller tube. I thus began, and under a tonic treatment, in which strychnia in rather large dose at that time (1/128th grain—0.0005 was frequently given three or four times daily), and in the eighth week I was able to relinquish the case.

Other cases, not as long as this, were frequently met with, and if I went into the third week I thought it nothing extraordinary.

Now, the change after the serum began to influence our methods, note the second case:

CASE 2.—William Henry W., aged 1 year and 6 months. American birth; patient of Dr. L. F. Taubel, of Philadelphia. Intubated with a No. 1 tube; and 1000 units antitoxin given with it; the general mercurial method of treatment.

With this case, I employed the services of advanced medical students. This child had been sick one week previous with a faucial diphtheria, for which the doctor had administered 1000 units antitoxin. This case then can be termed a "reinfection" and the result of a too small dose of the antitoxin, in an overwhelmingly infected child. As this patient had received 2000 units I felt, that after the third day all membranes should have disappeared; so on the fourth day of the intubation I extubated. I left the tube out one and a half hours, and reinserted, as there was need. The next day, I again extubated, but found I was again too early. On the sixth day I extubated and found the child could exist without the tube. The time required was 6 days and 16½ hours. In this case, had a sufficient amount of antitoxin been used in the first instance there would not have been the secondary laryngeal involvement, and intubation. This was a simple normal intubation.

CASE 3.—Lillie R., aged 5 years; female, of American birth and parentage. A patient of Dr. Augustus Kappes, of Philadelphia. Seen in consultation on the fourth day of its illness. Administered 2000 units of antitoxin at once, and intubated. On the sixth day the tube was withdrawn. Indications perfect, and the tube was not reinserted. Seven days thereafter, I was with the Doctor in another case—a male child aged 3, intubated, and tube withdrawn on the fifth day, cured—when Dr. Kappes told me of the beginning difficulty in breathing of the first case. As it was in the neighborhood I visited the case, and at once intubated again. There was the greatest need, as the child was almost in extremis. In this family were two other children, all girls, and older by a few years. In the one was a beginning tonsillar diphtheria; in the other a very pronounced faucial, almost malignant? Was this case reinfecting by the older sister? I injected 2000 units again, and in one week withdrew the tube, and it was no longer required.

**CASE 4.**—William S., twin, aged 1 year, 4 months. The other had died of diphtheria. Patient of Dr. Lawrence Wolff, of this city. I had no further work to do, simply to intubate. This child was of Italian parentage, and I have noted that a larger tube is sometimes required in these cases, larger than the average. I began with a No. 1 tube. After 5 days the child, in vomiting, expelled the tube. I reinserted, and as promptly expelled. I did this for a period of five days, when I used No. 2. After four days this was expelled, the child requiring further intubation, and the danger of expelling the tube when I was not to be had, prompted me to use a No. 3 tube. This I used for one week, when I began with a smaller tube, and so on until no longer required. This case required a tube thirty-five days. Of the method of treatment I had no knowledge, but it appeared to me that the child was so toxic that it required so much time for it to recover.

**CASE 5.**—A male child aged 5 years, in the practice of Dr. Moore, Bridgeton, N. J. This case was reported in the *Medical News* by the Doctor, and was essentially one of chronic croup. The interest in this case was the enormous (to us then) amount of antitoxin given during the course of the disease, over 22,000 units. The result was a recovery. This child eventually expelled the tube by coughing, and the croupy symptoms were manifested. He did not require the tube as long as the difficulty lasted.

**CASE 6.**—The last case I wish to record has already been placed on record, in *American Medicine*, No. 5, May, 1901. Herbert D., aged 2 years and 7 months, was treated by an insufficient amount of antitoxin, was reinfected on the seventh day with laryngeal symptoms, which three days later required intubation. The interest in this case consists in the fact that the cause of the prolonged intubation was found to be paralysis of the vocal cord, and hence treated therefor. The case required the presence of the tube thirty-six days, and the whole course of the child's illness from the beginning to the cure was forty-nine days. The case received 1000 units antitoxin as a beginning dose. The case was a tonsillar diphtheria. The result was a disappearance of all visual traces of the disease on the fifth day. The laryngeal symptoms were supposed to be catarrhal, simply because antitoxin had been given, and the toxin of the diphtheria supposed to have been nullified. The course of the disease, however, disproved this, and that the child suffered from paralysis, showed that the infection was profound, and the sequel a result.

The clinical history of the intubation was as follows: After the time (five days) had elapsed, when the membranes disappear (from three to five days) extubation was attempted. The result showing a disappearance of all stenotic symptoms. After thirty-six hours significant signs manifested the fact that at times suffocation seemed imminent; whilst, after a while, when the child was quiet, the breathing appeared natural. When the child was roused, as when crying or attempts at crying, a flap would be heard, as if a membrane was loosened, and then began the picture of membranous croup, ready for a tube. I intubated readily, and having used a larger tube than the age of the child required at the primary intubation, by reason of the normal size being too small, and giving no relief, I used the same sized tube. The large size of the tube, and the irritation caused thereby, gave me some trouble. I had edema, and at one time the tube was fixed by the swelling. However, I used but the gentlest local applications, until I could readily extubate, when I began the treatment for the prolonged intubation and the paralysis. The latter I treated with strychnia. Beginning at 1/100th of a grain (.00065) four times daily, until I reached 1/40th of a grain (.0015) four times a day. The intubation I treated thus: Until all edema and irritation had disappeared, I persisted with the large tube that I had begun with. After this I used the next size. This was expelled by coughing twice and reinserted. After the fourth day I used the smallest size. This proved what O'Dwyer had demonstrated in 1888, that a human being can breathe through a very small opening, if necessity compelled such a procedure. I think I am correct in the assertion made at the beginning of this paper, that O'Dwyer gave us a remedy for all the acci-

dents that might arise as a result of the tube. Surely this is a result of his work.

This paper would be incomplete if a detailed record of cases of prolonged intubation not ending as I described were not added.

While I have given my personal experience in the six cases thus described, I wish to give the experience of others, notably Dr. William M. Welch, of the Municipal Hospital, of Philadelphia. Inasmuch as I erroneously quoted Dr. Welch in a former paper on this subject, giving eleven months as a period, which should have been eleven weeks (See *American Medicine*, No. 5), and further, as I also listened to Dr. Welch's discussion of my paper, "Reduced Period in Intubation by the Antitoxin," read before the Medical Society of the State of Pennsylvania, May 21, 1896 (See Proceedings for that year), in which discussion Dr. Welch expressed views opposed to the author, I take this means of acknowledging that Dr. Welch was right in every respect, and that his discussion on this occasion is of such value that I feel a description of his cases would add materially to the value of this paper.

**CASE 7.**—The record of this case, and the one following was sent to me by Dr. Richard Reese, resident physician at the Municipal Hospital, and in charge of the diphtheria wards, in which capacity he is the intubator. For this reason his reports are more valuable.

Mary McG., aged 6 years. Admitted to the Municipal Hospital, May 3, 1900. Showed marked symptoms of laryngeal stenosis. Physical examination failed to show evidence of diphtheria in the fauces. The nares were dirty, but showed no distinct evidence of diphtheric involvement. The cervical glands were, however, distinctly enlarged. She had developed an eruption of measles twelve days previous to admission, and the laryngeal symptoms had been present for two days. Two successive cultures failed to show the specific bacilli, but a brother who was admitted at the same time showed clinical evidence of diphtheria, and cultures proved positive. This case unfortunately died.

The laryngeal stenosis required intubation on the following morning, the third day. Six days after intubation, on the ninth day of the disease, the first attempt at extubation was made, with failure, for reintubation was performed ten minutes after. Four days after (thirteenth day of the disease) extubation was again attempted, and the tube remained out for twenty-five minutes. Extubation and reintubation were performed at intervals of four days, three times, making it the twenty-fifth day, when the tube was permitted to remain longer, from six to ten days, with no better result. When extubated the child presented all the symptoms of laryngeal stenosis, marked dyspnea, repressions, sub-clavicular and sternal. Clammy perspiration, etc., till finally after forty-two days of this (June 15, 1900) the patient was finally extubated. Yet while the respirations were not entirely free, the patient was able to get a sufficient amount of air, without the need of the tube. Her general condition had improved greatly for about two weeks, the child was up, dressed and played with others, when the respiration became again noisy, and the stenosis progressively more marked, and relief was demanded. Recourse was had to intubation, but every attempt to do so failed. Dr. Reese attempted the intubation not only with the natural or normal tube, but with the smaller sizes, even to the infant size, and failed. As the case became more and more urgent for relief the Doctor performed a low tracheotomy. A slow recovery followed. The patient remaining in the hospital for ten months more.

Following the operation of tracheotomy, the patient became accustomed to these tubes, learned to speak and appeared comfortable. Even after the tracheotomy, attempts at intubation were made, but invariably failed. After the tracheotomy, cultures were again made, and the returns showed positive evidence of diphtheria.

CASE 8.—James L., an Italian, aged 4 years, admitted to the Municipal Hospital on Nov. 13, 1900. Examination showed no visual trace of exudate. The nares appeared irritated, the cervical glands were normal. There was, however, a diphtheric exudate on the upper and lower conjunctivæ of the left eye. In this case, intubation was performed at the home of the patient by Dr. Reese before taking the child to the ambulance for removal. A positive proof of the urgency of the case. The temperature on admission was 104.2, which fell gradually to normal on the sixth day, when extubation was first performed.

In this case cultures were positive both from the throat as well as the affected eye. Whilst the child was croupy but two days prior to admission, investigation proved that it was ill some five or six days before. Hence the first extubation was performed on the eleventh day of the disease. The tube was left out one hour, when it was reinserted. While the tube was out, the respiration was very much labored, but not enough to require the promptest intubation.

Four days afterwards extubation with reintubation in twenty-five minutes. Three days afterwards he was only able to breathe forty minutes, when intubation was again required. After four days the tube was coughed up. Reinserted, when again expectorated in twenty minutes. Dr. Reese then used a next size larger tube. This tube remained for two days, when it was coughed up, and it was necessary to reinsert at once after each coughing expectoration. The longest time he could do without the tube was twenty minutes.

On December 20, or after the thirty-seventh day of intubation, he began to cough up this large tube, when a still larger tube (i. e., for 8-9 years) was inserted. This was done with some difficulty, owing to the length of the tube, but the caliber of the larynx seemed sufficiently large as it did not fit too tightly. He continued to wear this tube until February 17, ninety-six days from the first intubation. Dr. Reese further reports to me: "We tried, of course, at intervals of from three to seven days to extubate, but with no more success, although at several of the later extubations the patient was able to breathe without the tube for an hour, and once, with some difficulty, over night." After wearing the tube for the time stated, it was removed one morning and the child breathed so well that reintubation was not necessary, and it was hoped and even thought that the difficulty had been overcome. For some days the patient did very well, breathing seemed easy, and unless one listened closely, the breath sounds were not audible. He continued doing well for nearly two weeks, when stenosis returned gradually but progressively. until sixteen days after the last extubation, when intubation was again required (the 117th day). This time the tube remained seven days, but again on performing extubation, it was necessary to reintubate in forty-five minutes. The tube was finally removed in seventeen days. The duration of this case (excepting the days when the tube was from the larynx) was 124 days.

Dr. Reese adds a very significant point: When the intubation was required after the lengthy extubation he could only use the normal size (i. e., four to five years) where before an extraordinary large tube had been used. Even this normal-sized tube appeared too large, and had to be inserted with some little force. "A permanent stenosis seemed to be coming on" and may possibly explain the case preceding this. Eighteen days after the last extubation, or on the 159th day of the disease, the stenosis had again become so marked that operative relief was urgently demanded. Intubation was again tried, but, as in the preceding case, it was not possible to insert an intubation tube. The larynx was almost completely closed, and as the child's condition demanded immediate relief, a tracheotomy was performed. This operation was done on April 15 last. The child has done well ever since, although, from that time until the present, he has passed through an attack of measles and chicken-pox.

As an appendix to Dr. Reese's report of this case: "It might be of interest for you to know, that during a greater part of the time that the child was wearing the tube, he was physically able to be up and dressed, and played about the wards of the hospital, as he is doing now. Not having been discharged, as I

wished to see what might be done in the way of dilating the larynx."

#### METHOD OF TREATMENT.

It is always best in treating diseases to prevent, and in diphtheria of the larynx our endeavor should always be to prevent the disease progressing so far as to necessitate intubation. For this purpose we have the antitoxin. If the serum be used early enough and in sufficient quantities we can cure even before a symptom so marked as stenosis becomes manifested. If, however, we are called when the tube is required and then find that an insufficient amount of antitoxin had been used we must, after the operation, administer more; or our cases may be changed from the normal to the abnormal, that is, from a simple intubation that may require five to seven days, to a prolonged one, when it will be impossible to prognose a future. As the consensus of opinion points to the method of treatment as one cause, we must endeavor to remedy this.

Next to the insufficiency of antitoxin as a cause, stands local treatment. The use of too strong local applications are certainly to be deplored and we must advise to use the utmost care. While it may be our purpose to keep the parts as clean as possible, we must use the gentlest means: Boric acid in water, soda bicarbonate with carbolic acid in a suitable mixture, as in the nasal or catarrhal affections; or, if we wish to use the peroxid of hydrogen, we must dilute it sufficiently. There never should be used the so-called solvents of diphtheric membranes made up by chemists who have never seen a case of diphtheria, and know less. The crime of asserting that certain remedies are useful or specific is a cruel one and should receive condemnation of all. How much harm has been caused? How little or no good? I have received monographs that tell of the specific virtues of certain remedies in this disease that are worse than criminal. I would not urge too much conservatism; for the sin of omission is often as bad as that of commission. But I would urge the necessity of a common-sense method of applying local measures in intubation, and I feel by such a course prolonged intubations can be, in a measure, averted and the cases progress in a normal way.

As for those cases of diphtheria in which the tube is retained and we are still treating, I think the opinion of all is the same: The frequent extubation with reintubation, by progressively smaller tubes, until the case no longer requires them. If, as in the cases of Dr. Welch, reported by Dr. Reese, this method of treatment does not avail, tracheotomy, as performed by them, is the only recourse; and it is the common practice of all so to do. Still, the question of Dr. Reese is a very pertinent one, the dilatation of the contracted parts.

Egidi has reported some devices in dilating the larynx by a double tracheotomy tube. This may be useful for contractions low down, but for those high up in the larynx some other invention is required. Dr. Reese, whose opportunities are greater than many of us, has promised to give this his earnest thought. I should be the one who would apply such procedure, but until we have such means and the method of using the tubes fails, tracheotomy is the only remedy.

The medical treatment is strychnia. Naturally, in this we must be guided by the cause. If used, it should be used fearlessly.

#### SUMMARY.

Intubation of the larynx has taken the place of tracheotomy in the treatment of diphtheria.

It is now used to a greater extent than ever before.

Those best versed in its use should define certain rules of practice, and these should be sufficiently plain for a novice to follow. The rule that I would lay down is: The tubes should be clean; if metal, they should be regilded; if rubber, a new one should be provided for each case; if the tubes are smooth, clean and correctly applied, the greatest part of the operation is attained, and that is, a clean, smooth surface, undefiled, which can remain in the larynx a week, or even two, and do no harm.

Hence, if the intubation be prolonged, the reason will be in the type of the disease, and no fault of the operator.

#### DISCUSSION.

DR. B. R. SHURLY, Detroit—During the last five years I have performed 261 intubations, using antitoxin, with a mortality of 60, the first hundred representing a mortality of 31, the second hundred a mortality of 20, and the last thirty operations giving 2 fatalities. Both of these patients had pneumonia at the time of operation. As these cases were scattered over a period of five years, we can readily see the remarkable encouragement offered by intubation in laryngeal diphtheria. According to the observations that I have been able to make, it would seem that prolonged intubations should be considered to be those in which the tube is retained over the sixth day. It has been my practice to remove the tube on the fourth day, and sometimes on the second day. I have had only eight cases of prolonged intubation—in other words, those in which it has been necessary to reintubate. It seems to me, therefore, that under a sufficient dosage of antitoxin, at least 3000 units, the tube may be safely removed on the fourth day. Under these circumstances intubation will not be required a second time except in a comparatively small number. In the eight reintubations already alluded to the tube was retained from six to twenty-three days. In the period of five years there have been over a dozen of these cases, and all have recovered except one. This patient died very suddenly on the thirteenth day, evidently from occlusion of the tube. As all of these cases were seen in private practice, they received absolutely no care farther than the administration of the antitoxin and the intubation. The great majority of these cases occurred among the pauper population and the work has been done under the greatest difficulties. I would say that the tube should be removed on the fourth day in a normal case.

In considering the causes of prolonged intubation I would make the same classification as that described in the paper. The most important cause, to my mind, is traumatism. A number of cases met with have come to me from the hands of other operators, and they have presented extensive traumatism, sometimes a band of cicatricial tissue being found at the entrance of the larynx. A second important cause is an ill-fitting tube. The plated tubes should be avoided because any defect in the plating will lead to calcareous deposits upon the tubes, and these must cause further injury to the delicate lining membrane of the larynx.

DR. S. J. K. GOLDEN, Chicago—I have used the suprarenal extract in doses of 2 grains every three hours, and although all but one of the cases was not very bad, I found that the edema of the larynx disappeared, and the tube was coughed up or would be pulled out by the child. It is my practice to leave a piece of silk attached to the tube.

DR. I. A. AET, Chicago—It seems to me that the sooner the tube can be taken out, the better. The practice formerly in vogue in Wiederhofer's clinic was to remove the tube every morning, and I believe it is a useful plan. I think it is an excellent practice to remove the tube during the first twenty-four hours. If the dose of antitoxin has been sufficiently large, and it should be made so, the tube can and should be removed early. I think in Chicago many of us remove the tube after twenty-four hours.

If one reads text-books and listens to his colleagues he rarely

hears of difficulties met with by experienced intubators. It is true that rupture of the larynx may occur, and also pushing down of the membrane, but there are also cases of impossible intubation. Dr. E. Fletcher Ingals has reported several such, as has also Ranke of Munich, and others. Last winter I presented to the Chicago Medical Society a case in which I had endeavored to introduce the smallest tube, the child being between eleven and twelve months old. I found that I could introduce the tube into the larynx, but that if I placed my finger on top of the tube the successful completion of the operation was impossible without the employment of unjustifiable force. I, therefore, desisted from these attempts and performed tracheotomy. The child died in twenty-four hours, and the autopsy was done within a very few moments after death. I found it still impossible to introduce the tube in the larynx of the dead child. From my experience in this case I maintain that there are occasional cases in which it is impossible to insert a tube into the larynx.

DR. LOUIS BURKHARDT, Indianapolis—The idea of performing intubation in the country and leaving the case in unskilled hands is a serious matter. I used to remove the tube after twenty-four hours, and sometimes I introduced it three or four times a day and observed very few bad results from pressure. If, as the essayist assures us, the tube can stay for six or seven days without doing any injury, it is a great practical advantage. The idea advanced by the gentleman from Chicago regarding the use of adrenalin seemed to me useful; however, it would seem to me that the local use would be better than its internal administration. Under the influence of decreased circulation the swelling of the mucous membrane will be reduced, and in some cases it might even be possible in this way to get along without intubation.

DR. E. ROSENTHAL, closing—I use metal tubes, but always have them regilded after each use of them. The cost is only about 75 cents. I have this done every time I use the tube, even though it is several times in the same case. I have used hard-rubber tubes, but have been unfortunate with them, finding that they are subject to the formation of calcareous deposits also.

#### AN OPERATION FOR SPINA BIFIDA, WITH REPORT OF A SUCCESSFUL CASE.\*

LEONARD FREEMAN, M.D.

DENVER, COLO.

A spina bifida is a hernia of the membranes surrounding the spinal cord through a congenital opening in the posterior aspect of the spine. Very rarely there is also a defect in the bodies of the vertebræ. The sac is always filled with cerebrospinal fluid, and often contains nerves from the cauda equina, or a portion of the cord itself. The sac is usually covered by integument, but this is frequently so thin as to be translucent. The opening may be so small that it will scarcely admit the finest probe, or it may extend from the foramen magnum to the sacrum. Extensive deficiencies are, however, very rare. The tumor is usually located in the lumbo-sacral region, although it may appear at any point along the spine. It may be large or small, pedunculated or sessile.

A meningocele is a hernia of the membranes containing fluid only; a meningo-myelocele contains also a portion of the cord or its nerves; and a syringomyelia consists of the dilated cord with fluid in its central cavity. The last named variety is rare, and perhaps incurable, the other forms being usually encountered.

Clubfoot, hydrocephalus, vesical exstrophy and various paretic and paralytic conditions of the lower extremities, bowels and bladder are occasionally met with.

Although spina bifida is not a common affection, it appears sufficiently often to deserve careful attention.

\* Read before the Rocky Mountain Interstate Medical Association, Denver, Colo., Sept. 4, 1901.

about once in from 800 to 1000 births, constituting about one-sixth of all congenital deformities. Rarely a spontaneous cure takes place through gradual closure of the opening, but in nearly all untreated cases rapid growth occurs, resulting in rupture followed by meningitis and death.

Many procedures have been employed for the cure of spina bifida, the principal being: Simple pressure, by means of flexible collodion or an elastic bandage; aspiration followed by pressure; insertion of setons; injection of irritating fluids, such as tincture of iodine, alcohol, etc.; clamping or ligating the neck of the sac, subcutaneously or not; and lastly, the open operation, in which the sac is surrounded by elliptical incisions and partially or completely removed according to the nature and arrangement of its contents.

After the edges of the abbreviated sac have been stitched together with catgut the operation may be completed in one of several ways:

1. The skin and subjacent soft parts are united over the opening by means of deep sutures.
2. The defect is covered by fascia and tendons, or by periosteal flaps obtained from the bony surfaces on either side.
3. Portions of bone may be chiseled from the sides of the opening and united in the center line.
4. A fragment of bone with a pedicle of muscle is obtained from the iliac crest or an adjacent rib and swung over the opening.
5. Bone or cartilage from a rabbit or other animal is utilized.
6. Very recently it has been suggested to spring a celluloid plate into the spinal defect.

As to the choice of methods, aspiration and compression are very unreliable, and their employment should be limited to tumors of small size and slow growth, with a covering of comparatively normal skin. They may also be temporarily used to prevent rupture when waiting for the patient to gain in strength or age, with the idea of doing a radical operation later on.

Injection of irritating fluids, although uncertain, has been much used and is often effective, at least temporarily. The method carries with it considerable risk, especially when the aperture into the spinal canal is large. It is asserted that hydrocephalus is peculiarly liable to supervene from the resulting irritation. Its greatest usefulness is in pure meningoceles with small openings or with pedicles which can be compressed during the injection.

Setons, or continuous drainage, should never be used. There is too little likelihood of cure and too much danger of infection. Clamping or ligating the neck of a pedunculated tumor is almost certain to give rise to sloughing and infection leading to fatal meningitis.

There remains the open method of operating, which, under the modern aseptic regime, is preferable to any other. When carefully done it is, perhaps, no more dangerous to life than most of the older procedures, while it offers a better prospect of permanent cure. It permits inspection of the contents of the sac, thus avoiding injury to the cord or its nerves, and it renders possible a solid closure of the opening. In other words, spina bifida should be treated like any other hernia, the possibility of doing this with comparative safety resting upon rigid asepsis. It was thought to be impossible a few years ago. Bardeleben, for instance, in 1867, says of the operation: "It is too dangerous in comparison with its advantages, and should be completely discarded."

In estimating the comparative advantages of the various open operations, we must consider not only the ultimate results, but the age and resisting powers of the patient. In the majority of instances we have to deal with very young and feeble babies, who will not tolerate prolonged anesthesia or extensive manipulations. Owing to this and to the minuteness and delicacy of the structures, it is often impossible to procure bone or periosteal flaps, or to do complicated plastic operations of any kind. Hence, until recently, the most practical procedure has consisted in removing the sac, stitching its remnants over the cord, and uniting the soft parts and skin above. Although this has given fairly good immediate results, it does not guard sufficiently against relapse, especially when the opening is large and the child inclined to cry.

The transplantation of bone from an animal is theoretically attractive, but it is troublesome, to say the least, and exposes the patient to considerable risk of infection. A celluloid plate is not readily cut to a size that can easily be "sprung into the opening," as has been suggested, and if it is not accurately adjusted it may slip or turn partially on edge and thus irritate or compress the nerve structures beneath.

In operating on a case of spina bifida not long ago it occurred to me to employ fine silver wire in closing the aperture in the vertebral column, and I found it admirably suited to the purpose. After placing the nerve structures and remnants of the sac within the canal, a continuous over-and-over suture was readily and rapidly inserted, from one side of the opening to the other, through the periosteum and ligaments, and occasionally through the bone itself, the stitches being close enough together to form a firm covering for the cord, incapable of displacement by any subsequent movement or straining on the part of the child.

Silver wire is always at hand and readily sterilized, and it adapts itself to any form or size of opening. That it can remain permanently in the tissues without causing disturbance has been abundantly demonstrated by the innumerable instances in which it has been used in wiring bones and suturing other subcutaneous structures.

I have elsewhere expressed the opinion that it is unnecessary to suture the spinal membranes in the majority of instances. I have followed out this idea in a number of cases without cause for regret. It applies to operations for spina bifida as well as to other procedures. The remnants of the sac fold into a mass which plugs the opening and is held in place by the covering of wire, and adhesions soon take place which render sutures superfluous. A certain amount of danger of catgut infection is thus avoided, and considerable valuable time saved.

Dr. H. O. Marcy insists on the value of the Trendelenburg position, asserting that gravity will materially assist in the prevention of the escape of the cerebrospinal fluid. This seems to be open to question, to say the least. The fluid is contained in a rigid tube, closed everywhere except at its lower end, just as if it were within a pipette with a finger over the upper opening. The only way it can run out is by depression of a fontanelle, which can not displace a great quantity; or by the entrance of blood into the cranio-spinal cavity to take the place of the fluid. In the Trendelenburg position the flow of blood into the skull would be greatly facilitated, and I am inclined to believe that the loss of cerebrospinal fluid would perhaps be greater in this position than in any other. The loss of fluid, however,

is probably much more strongly influenced by the size of the aperture between the subdural space of the cord and that of the brain, and by crying, choking or straining under the anesthetic, than it is by any particular position.

I herewith append a brief report of a case upon which I successfully operated according to the method outlined above.

Baby H., 7 weeks old, healthy, well developed, and without deformity other than spina bifida. A translucent tumor the size of a goose-egg existed in the lumbo-sacral region. The sessile sac, not larger than the end of a thumb at birth, had steadily increased in size until the integument had become translucent and as thin as tissue paper, threatening rupture at any time; in fact, a slight leakage had already taken place.

Under chloroform, in August, 1901, an elliptical incision was carried around the tumor near its base, and the sac, which was intimately adherent to the attenuated skin, was opened at once. The elongated conus was freed from its central attachment to the sac and replaced, together with some nerve filaments, within the opening, which just admitted the point of a finger. The sac was then cut away near its base, the neck freed from its attachments to the edge of the cavity and stuffed into the opening onto the cord. The aperture was then whipped over as described above with No. 27 silver wire, the soft parts and skin being brought together with deep silkworm-gut sutures. The wound was sealed with collodion and supported as well as possible with a compress and bandage. The further progress of the case was uneventful and led to satisfactory recovery. In spite of primary union taking place there was some rise in temperature, as has frequently been noticed by others.

Although the immediate result was everything that could be desired, the ultimate fate of the child is yet to be determined. That the tumor itself will recur is extremely unlikely, but it is a fact that many such cases finally succumb to hydrocephalus.

#### CASE OF THOMAS P. BODEN, THE CONSUMPTIVE IRISH IMMIGRANT.

ITS MEDICAL, SOCIOLOGICAL, INTERNATIONAL AND HUMANITARIAN ASPECT.

S. A. KNOPE, M.D.

NEW YORK CITY.

If Mr. Francis Tracy Tobin, the counsel for Thomas P. Boden, the Irish immigrant now detained by the immigration authorities because he is consumptive, should succeed in bringing this case before the Supreme Court of the United States, this, the highest tribunal of our country, will have to decide a most momentous question. The issue involved not only affects the few consumptive immigrants who may arrive at our ports, but it affects the several million American citizens suffering from pulmonary tuberculosis.

On the strength of a declaration of the surgeon-general of the Marine-Hospital Service that pulmonary tuberculosis is a dangerous contagious disease, the superintendent of immigration issued last June an order that in future immigrants with tuberculosis of the lungs must be debarred from all ports of the United States regardless of boards of special inquiry, which heretofore had used their discretion in the matter. Formerly the board of special inquiry at this port, after receiving the report of a case of tuberculosis from the chief of the medical division of the immigration service of New York, could exercise discretion as to the admission of the person, and there have been instances in which a child ill of the disease has been permitted to land with its parents; but henceforth no one with consumption will be admitted to the country. This rule applies to alien passengers in

the first and second cabins as well as to those in the steerage.

Is this declaration issued by the surgeon-general of the Marine Hospital Service, and strengthened by the authority of the Treasury Department, based on scientific observation? Is this opinion shared by other great authorities on the question of tuberculosis and the medical profession of the United States in general?

Ever since the discovery of the tubercle bacillus it has been demonstrated by clinical and bacteriological experiments all over the civilized world that the germ alone is the direct cause of the disease, and without its presence tuberculosis can not be conveyed. The bacilli are usually contained in the expectoration, more rarely in other secretions, very rarely in the muscular or osseous tissue. Thus the contact *per se* of a consumptive individual does not transmit the disease, and pulmonary tuberculosis is not a contagious but only a communicable malady. The destruction of tuberculous expectoration and other secretions, also of tuberculous food substances, suffices to do away with all danger of infection and transmission. Therefore, there is no scientific basis on which to classify pulmonary tuberculosis among the dangerously contagious diseases, and it is contrary to the results of experience and experiments of all who have studied the question thoroughly.

Now, what have the great European and American medical authorities to say on this subject? Koch, the discoverer of the tubercle bacillus, says in this connection in his recent London address, which I quote verbally, since it was delivered in English: "A consumptive who coughs out tubercle bacilli is not necessarily a source of infection on that account so long as he takes care that his sputum is properly removed and rendered innocuous." Professor Herman M. Biggs, whose splendid work in the prevention of tuberculosis has been most highly commented on by Koch in the same address, declares in the circular issued by him through the New York Health Department: "If the matter coughed up be properly destroyed a person suffering from consumption may frequently not only do his usual work without giving the disease to others, but may also thus improve his own condition and his chances of getting well." This circular has served as a model to many health boards in this country and abroad. Concerning the action of the Treasury Department in regard to tuberculous immigrants—not paupers—Dr. Briggs pronounced it unscientific, unwise, unnecessary and inhumane. Dr. T. Mitchell Prudden, professor of pathology and bacteriology at the College of Physicians and Surgeons, declares distinctly that pulmonary tuberculosis is a communicable and not a contagious disease.

For the United States government to declare pulmonary tuberculosis to be a dangerously contagious disease, in spite of the opinions of these great authorities, stamps several millions of American citizens suffering from consumption with a stigma wholly undeserved. That the general profession is in thorough accord with the opinion expressed by Professors Prudden and Briggs may be gleaned from editorials which appeared in three of the leading American medical journals. Dr. Frank P. Foster of the *N. Y. Medical Journal* says in an editorial of June 22: "It is our conviction that the United States Bureau of Immigration, if it has really determined upon the course of indiscriminately excluding consumptive immigrants from the country, as has been announced, has been ill-advised. . . . What the people need to be taught—and they have already partly

learned the lesson—is, not that pulmonary tuberculosis is a monster to be fled from, but that it is a danger that can be effectively overcome. Even if this were not true, it remains a fact that the policy of selfishness and inhumanity, pursued to the end, rarely if ever proves to be for the general welfare of those who follow it." Dr. George M. Gould, in *American Medicine*, of November 30, says in the leading editorial entitled "The Deportation of Consumptive Immigrants": "We think professional and lay opinion will not justify the exclusion of tuberculous immigrants on the simple ground that the disease is 'contagious' or 'communicable.' It is only so in such a low degree that the severe measure of exclusion for this reason alone seems unjustifiable." Dr. George H. Simmons, editor of THE JOURNAL A. M. A., in criticizing the indiscriminate exclusion, says: "Even hopeless consumptives may sometimes bring some good," and cites Robert Louis Stevenson as an example.

The government decision to classify pulmonary tuberculosis as a dangerously contagious disease has only been in operation a few months, but it has already had its consequences by increasing the fear of people to associate with consumptives. Healthy employees have been discharged because some one of their near relatives with whom they were living were reported to their employer to be suffering from consumption. I have learned of numerous similar cases and very recently two came under my personal observation. A sewing woman who had been employed frequently by a wealthy family mentioned incidentally that her sister was being treated for tuberculosis of the lungs, but was getting along very nicely. The result was that the poor woman was discharged and never employed again by the same family. A similar case happened within this week with a poor washwoman. How much suffering and hardship may thus be daily created only those who come in contact with the poor consumptives can appreciate. All physicians will approve of earnest and intelligent measures to prevent the spread of tuberculosis, but to exaggerate the danger by declaring consumption, which is a chronic, preventable, curable and only a communicable affliction, to be a dangerously contagious malady, we only create another disease in the minds of the people which may justly be called phthisiophobia.

By excluding pauper immigrants, whether tuberculous or not, the immigration authorities do their duty, and every loyal American citizen must approve of it; but by excluding consumptive aliens of means, or at least such who can give evidence that they will not become a burden to the community, we may subject ourselves to retaliatory measures on the part of other governments and wealthy American pulmonary invalids may no longer be allowed to enjoy the hospitality of foreign health resorts. Thus this case has an international as well as a national aspect.

Concerning the humanitarian view of the case I have to add but little to the expression of Professor Briggs and Drs. Foster and Simmons. Since the ruling of the Secretary of the Treasury that pulmonary tuberculosis is a dangerous contagious disease within the meaning of the statute, all certified cases of tuberculosis are returned without discrimination. Parents may thus be separated from their children, brother from brother, sister from sister, friend from friend, because of a law founded on an unscientific basis, contrary to all sociological interests of our own country, derogatory to our interests and in our relation to other countries, contrary to the American spirit of justice and humanity.

Have those who by this decision stamped every American consumptive as one afflicted with a dangerous contagious disease ever thought how really few families there are who have not at least one, more or less near, relative or friend who is a consumptive? Tuberculosis is the most frequent of all diseases and it is most prevalent in its pulmonary form. It is a disease of the young and the old, the poor and the rich, the East and the West, the North and the South.

May the wise judges of the Supreme Court, who it is to be hoped will soon be called to consider this matter, view it in all its aspects and decide it in the light of our present knowledge which makes the consumptive not a hopelessly ill individual, afflicted with a dangerously contagious disease, whose contact we have to fear, but which declares him only suffering from a communicable and at the same time easily preventable, and in many instances very curable disease.

### THE USE OF TROPA-COCAIN IN SPINAL ANESTHESIA.\*

WILLIAM P. ILLING, M.D.

LITTLE ROCK, ARK.

At the last meeting of the Arkansas State Medical Society I read a paper on my experience with spinal anesthesia and reported 23 cases in full. In that paper I gave the technique and method of preparation in detail, and will not now consume your time by their repetition.

Since last May I have had a varied experience with spinal anesthesia, having used the method on 80 different occasions. These comprise six obstetrical cases, of which three were instrumental deliveries—four multiparae and two primiparae. Two of these suffered from lacerated perineum—one a primipara, the other a multipara. In these six cases twenty minims of a 2 per cent. solution of cocain hydrochlorate was injected. These cases did not differ from any of the others on which I had used this method, the anesthesia appearing in the usual length of time and lasting one hour and ten minutes in the shortest case and one hour and forty minutes in the longest.

Twenty-five other cases were for the following operations, namely: perineal abscess, two gunshot wound of the foot and shattered bone removed, one; hemorrhoids, six; curettage, nine; lacerated perineum, two; lacerated cervix, two; dilatation of urethral stricture, one; amputation of foot, one; removal of portion of necrosed tibia, one. In these cases I used cocain hydrochlorate in the usual manner.

The largest amount of cocain hydrochlorate used in any case was twenty minims of a 2 per cent. solution, or  $2/5$  grain, producing anesthesia lasting one hour and fifty-six minutes; the smallest amount used was ten minims of a 2 per cent. solution, or  $1/5$  grain, producing anesthesia lasting only twenty-three minutes.

I will now confine myself to the 49 cases in which I used tropa-cocain and to which this paper refers.

In my first paper I mentioned that H. Schwartz of Leipsic reported, March 2, 1901, having used tropa-cocain in sixteen serious operations, with none of the toxic effects usually observed in the use of cocain hydrochlorate. Dr. Willy Meyer<sup>1</sup> of New York reports having used tropa-cocain on three different occasions with all the satisfaction that could be desired from an ideal

\*Read before the Northwest Arkansas Medical Society, at Fayetteville, Ark., Dec. 3, 1901.  
1. Medical News, April 13, 1901.

anesthetic. These flattering reports stimulated me to try it. Many of my cases were patients of prominent surgeons in the city and all were at the Pulaski County Hospital. Among the operations were: three laparotomies, three amputations of legs, one amputation of thigh, two amputations of toes, ten curettings, one resection of necrosed rib, one varicocele, three excisions of indurated inguinal glands, six dilatations of strictures of urethra, one fistula in ano, five hemorrhoids, three lacerated cervix, four openings of deep abscesses, three curettings of old indolent ulcers, one hernia, two lacerated perineums; total, forty-nine.

In 1891, Geisel discovered tropa-cocain in Javanese coca leaves, after which it was more closely studied by Liebermann, later Willstatter discovered a way of preparing it from tropin, a fractional product of atropin and hyoscyamin. It is now universally prepared by the decomposition of atropin and hyoscyamin, and occurs in colorless needles readily soluble in water.

It admits of thorough sterilization by boiling, a virtue which is widely proclaimed for it; yet when it is boiled from fifteen to twenty minutes it is my opinion that the anesthesia lasts only one-half as long as when it is prepared by heating the cocain solution in an autoclave or water bath which is brought to 176 Fahrenheit for fifteen minutes, then allowed to cool three hours. This procedure is repeated four or five times, having the cocain solution in a glass-stoppered bottle. This method is a little slow but it insures a thoroughly sterile solution. (I have repeatedly boiled the solution and find it about one-half the strength it was before boiling.) Tropa-cocain is less than half as toxic as cocain hydrochlorate, the relation between toxicity and dose is more constant with tropa-cocain, and therefore the unexpected toxic effects are much less liable to be met with.

Recovery from its effect is much more rapid. Upon the nerve centers it acts by first stimulating, then paralyzing from the brain down in decreasing degrees, but it prevents complete paralysis of the spinal cord or respiratory centers. I think its action is a little slower than cocain hydrochlorate. I find in using cocain hydrochlorate the anesthesia usually appears in from four to ten minutes, while with tropa-cocain it seldom appears earlier than ten minutes. After trying eucain B., cocain hydrochlorate and tropa-cocain repeatedly, I believe that tropa-cocain is far superior for spinal anesthesia—in fact I believe it can in many cases replace cocain hydrochlorate.

After an injection of tropa-cocain there is usually no complaint of thirst, heat, vomiting, pallor, nausea, perspiration; no marked increase or decrease in the pulse; no facial expression of anxiety; no marked increase or decrease in respiration; no dyspnea; but I have noticed relaxation of the sphincters, with involuntary evacuation of feces, in two of my cases, which occurred while the patients were on the table; in one the bowels continued to move after being returned to bed. Tuffier recommends plugging the bowels with a tampon to avoid this inconvenience. In one of my cases the patient complained of the motion in his bowels, which caused him great inconvenience. Fowler also calls attention to the vigorous peristalsis of the bowels. I have as yet noticed no idiosyncrasy for the drug.

Schwarz reports using five-sixths of a grain at one injection with complete anesthesia lasting two hours, but Meyer reports shorter periods of anesthesia in his cases and the use of one and one-half grains at two injections, fifteen minutes apart, in the same person,

which is to my knowledge the largest amount ever injected. Yet this amount did not produce any more severe symptoms than are sometimes witnessed with an injection of twenty minims of a 2 per cent. solution of cocain hydrochlorate.

The largest amount I have ever used is one grain—in one case in a rectal operation, and in another in curetting a large ulcerated surface. It produced anesthesia lasting three hours and eight minutes in one, and one hour in the other. The difference in the length of anesthesia is, in my opinion, due to the fact that the solution lasting only one hour had been boiled; and the other lasting a little over three hours had only been heated to 176 F. in a water bath. It is my belief that to obtain perfect anesthesia we can safely count on one-sixth of a grain of tropa-cocain to produce anesthesia fifteen minutes, and sometimes even longer.

I have given a hypodermic injection of one-fiftieth of a grain of nitro-glycerin immediately before the spinal injection, and have used the sodium-chlorid in combination with the tropa-cocain as used by Meyer; but my experience with it has not been very gratifying, the patient invariably complaining of the intense headache after its use. I now use hyoscin hypodermically about ten minutes before the spinal injection, and leave out the sodium chlorid. My method of preparing the solution is to allow one grain of tropa-cocain for every dram of water; and always prepare a little more than is needed. Thus every ten minims of the solution contains one-sixth of a grain of the drug.

I predict a very useful field for spinal cocainization in surgery, and from my experience I do not hesitate to urge its use with as much confidence of success as I do chloroform or ether. I do not think it will ever be successfully used in abdominal surgery, on account of the tendency to vomit and intestinal peristalsis; neither am I favorably impressed with its use in obstetrics. However, in obstetrics, I could not be emphatic since my experience extends only to ten cases.

## OUR HOSPITALS.\*

H. D. NILES, M.D.

GYNECOLOGIST TO THE HOLY CROSS HOSPITAL,  
SALT LAKE CITY, UTAH.

The evolution of the hospital—including the growth and development of hospital work—has, in recent years, been so rapid and so far-reaching that comparatively few people in or out of the profession realize that these institutions have already become one of the most potential factors in progressive medicine, and that the time is not far distant when they may exercise an influence over the destiny of medicine greater than all others combined.

Originally intended by their benevolent founders simply as temporary homes where the sick poor might secure proper medical care and nursing, the peculiar advantages of hospital appliances, methods and nursing soon became favorably known to all classes; good men early became identified with the enterprise; medical students sought these places for clinical instruction; people of means contributed to their support and the hospital enterprise continued to grow in prosperity and usefulness.

Hospital boards and the general public, who have been content to measure this prosperity and usefulness by the number of patients treated, the lives saved, and suf-

\* Read before the Western Surgical and Gynecological Association, Chicago, Dec. 17 and 18, 1901.

ferings mitigated in a given period, are well satisfied with the results and see no occasion for changes in methods or purpose. Such an estimate is manifestly inadequate, since the largest and best part of a hospital's good work can not be thus computed or even comprehended by the non-professional mind.

Even the profession as a whole, each member of which employs in his daily practice, methods of diagnosis, means of treatment, operative procedures, bacteriologic and microscopic data, and statistical information derived directly from the hospital, is prone to underestimate the power the hospital possesses as a promoter of medical progress or the good it accomplishes in the cultivation of a spirit of scientific investigation and in furthering the efforts of good men to advance medicine. It has been said, and I think truly, that if we as physicians should forget all the knowledge gained by the past fifty years of hospital achievements, medicine would be set back at least a quarter of a century, while to eliminate the hospital's influence upon progressive medicine for the next fifty years and depend upon individual work alone would mean the return of empiricism.

The general practitioner who is, has been, and I trust always will be, regarded the highest type of physician, and who comes into contact with the largest proportion of human sickness and suffering, must now confess his dependence upon his hospital colleagues, or fail in doing his full duty to his patients. It is preposterous for any one individual to claim to be able to attend to a large practice, keep himself in touch with the best thoughts in general medicine, surgery, and the several specialties, and perfect himself in bacteriology, microscopy, hematology, x-ray work, pathology, and certain unusual operative procedures, and at the same time conduct the laboratory work incidental to such a practice.

He might, if quite frank, confess further that it is from his association with these workers in their special fields, his acquaintance with their methods and lines of thought, and the original researches and discoveries made in their laboratories, that he receives a large part of his practical knowledge and skill and his greatest inspiration to advance in his professional studies and work.

This is distinctly an age when great combinations of special forces rule the world, control all its enterprises, and govern the destinies of every undertaking of any magnitude. In medicine there is to-day a greater need for an exhibition of this same progressive spirit of the times than ever before. We must *combine* our special forces if we are to meet the necessities of the new existing conditions. For now as never before, it is apparent that our next great advances are to come from and will be dependent upon those researches, experiments, investigations and studies that can be prosecuted only where an abundance of clinical material and painstaking laboratory work are associated; where the clinician and operator can be in the closest touch with the bacteriologist, microscopist and pathologist; where the practical conclusions of the experienced man may be fairly compared with the theoretical deductions of the recent graduate; where the views of the skilled specialist and the general physician and surgeon are broadened by frequent consultations; where trained assistants and needed equipments are provided and it is possible to have accurate records kept and reliable statistics compiled. This combination is essential to our future progress as well as to our present efficiency, and can be pro-

vided only in our hospitals and through the labors of such hospital workers as are willing to concentrate their thoughts and limit their efforts to a narrow part of the great field of medicine, and leave to the general practitioner and family physician the wider and more practical application of the sum of their united labors.

It is very evident to the minds of medical men familiar with the situation that the methods and management that have served our hospitals so well when their purpose was limited to the care of the sick within their walls will not suffice if our hospitals are to meet our present needs and fulfill their possibilities as a great system of scientific institutions distributed throughout this country, where not only the favored few but the whole profession with all the sick intrusted to their care may feel the results and participate in the benefits. It is not enough that our hospital authorities provide and equip rooms where a promiscuous assemblage of physicians may be permitted to occupy their leisure moments trying to sustain the scientific reputation of their institution by unsystematic and irregular work.

We need to be as methodic, discriminating and earnest in our efforts to establish and maintain a truly scientific institution as those who control and direct our other institutions of learning. Our needs are somewhat similar and quite as great; and it is fair to presume that if much the same methods were applied with equal judgment the results would be as satisfactory.

Viewed from this standpoint, the staff would also be the faculty; the departments would be transformed into definite and distinct realities, each presided over by a member of the staff, who would be a specialist. The positions would be filled by men selected less on account of their personal popularity and more because of their proficiency in particular lines and devotion to certain branches. The size of the hospital staff would be reduced to conform to its actual needs as a scientific institution, for upon its standing as such, more than the bulky size of its staff, the hospital would depend for a following. The staff perfectly adjusted to the hospital's requirements would bring a harmony of action, a unity of purpose, and a general effectiveness not conspicuous in the large unwieldy staffs of to-day.

So long as a hospital measures its own usefulness by the number of patients treated, the standing of each member of the staff will be estimated largely by the size of his personal following; and the commercial spirit will rule both the institution and the individual to the exclusion or great detriment of scientific work. It so happens that many hospital men are engaged in special lines of study and investigation that prevent their attracting or attending many patients; yet the immediate and remote results of their work may be of the utmost importance to progressive medicine. These men deserve and should receive every encouragement; and it is manifestly unfair that their positions, income or professional standing should be dependent upon the number of patients they bring to the hospital. One of the effects of introducing the educational feature into our hospitals would be a more equitable adjustment of credit and remuneration, so that the laboratory worker as well as the operator would be fairly appreciated and compensated.

Our hospital statistics are already quite an important factor in medical literature, but with the scientific spirit prevailing over the commercial, the records of the work and achievements of these institutions might, and I

believe would, exercise an influence upon medical thought greater than all others combined.

But the fixing of a new purpose upon an old institution under the control of kind and well-meaning friends, who are content with the old aims and distrustful of the new, will require something more than college methods or college training. The medical profession can not reasonably expect to have much of a voice in this or any other reform measure until they revolutionize their present business policy and methods.

The prevailing ideas deprive them of not only the proper recognition and the adequate pecuniary recompense, but of the legitimate influence that justly belongs to the faithful and effective work of a learned profession. For this unfortunate state of affairs we can blame only our own defective business foresight and tact, since for years we have been educating and drilling the people to think lightly of our work, our comfort and our aspirations.

In the most prosperous country in the world, where the public is abundantly able to bear all its burdens, even to caring for its sick poor, the members of the medical profession, in and out of the hospital, have at all times, with and without provocation, held themselves up as shining targets for the impecunious, the mean-spirited and the unscrupulous to practice their impositions upon. They have sought out and assumed unnecessary responsibilities and cares without pay or reward. When in need of public or legislative aid they have intuitively and invariably attached themselves to the side of the minority. Individually and collectively they have rarely missed an opportunity to demonstrate their business incapacity. For many years the business methods of the profession have apparently served but one useful purpose, viz., as an example for the youth of our country to shun; and it is a significant fact that the only organization to-day that has thought well enough of these methods to adopt them is the Salvation Army.

Is not the physician who gives \$25,000 worth of his services to the hospital entitled to the same consideration as the rich benevolent layman who donates his \$25,000 in cash? Should not the ten physicians who thus contribute \$250,000 receive the same recognition that is accorded the multi-millionaire whose gift of a quarter of a million costs him no real sacrifice of time or enjoyment? Fairly estimated, do not our services justly entitle us to a voice in all professional questions in and out of the hospital, second to none, even to that of those benevolent individuals, charitable organizations or religious societies that founded these institutions?

If we are ever to secure this voice—and we need it now—we must formulate and adopt a business code that shall not only meet the highest requirements of the ethics of the profession but at the same time command the respect and win the confidence and support of this twentieth century public.

It must be admitted that a very considerable majority of the profession is not in close sympathy with our hospitals at present, and not a few are disposed to regard these institutions as the abiding place of a favored few where the outside physician may contribute much and get little in return. Awaiting a fair and amicable adjustment of these differences, imaginary and real, and the securing of the cordial coöperation of the united profession, all these physicians and their patients are deprived of available hospital advantages, of which they are in the greatest need, and our hospi-

tals are denied the very support most essential to their greatest success. In deciding such cases—and they should be decided—the common interests of the many should outweigh the individual interest of the few, and each of us should be willing to make any reasonable sacrifice or concession in the interests of our profession, our patients and our institutions.

Time will not permit our dwelling upon the many obstacles that threaten to retard the advance of our hospitals to the exalted position they can and should occupy, but among the most important questions that call for solution may be mentioned:

1. How shall the financial and professional relations between our hospital men and our general practitioners be adjusted so that *all* may be interested in the welfare and participate in the benefits of specialized hospital work?

2. Is there any good reason why our hospital men and hospital authorities—sheltered as they are behind a strong combination—should be exempt from the application of the same "Code of Medical Ethics" that governs the conduct of the profession generally?

3. Is the general practitioner to have any place in the hospital of the future?

4. Is the specialist of the future to have any place out of the hospital?

5. Do we not need more hospitals and fewer colleges; better doctors and fewer graduates?

6. In the present state of our knowledge, when the life and health of our patients so often depend upon special knowledge and skill or nursing, is any physician justified in assuming the responsibilities of a general practice except he be in touch with some hospital or hospital worker?

7. In view of the important relations our hospitals are destined to hold with progressive medicine, is it not about time the professional mind began to dominate in the control of these institutions?

These are a few of the many questions that are suggested to the minds of all who thoughtfully consider the hospital work of the past and present and are led to appreciate the marvelous possibilities of the future.

The object of this paper is not to volunteer instruction, but to arouse, if possible, a more active interest in an institution that promises with our aid to become one of the most influential elements in the medical world—its labors, its literature, its thought, its discoveries and its advances.

"How are our hospitals to meet the needs of modern medicine?" is, to my mind, the most important question before the profession to-day. I am quite aware that its satisfactory solution will not be the work of a day, nor of a single individual, nor of any clique or society of physicians; but I do believe that the medical profession as a whole, if united and determined, can decide upon and dictate an answer that should render the achievements of this twentieth century the most memorable in the history of medicine.

---

**Spontaneous Evacuation of Cyst in Pancreas.**—Monin describes in the *Lyon Med.* of September 15, the case of a woman of 28 who had passed through three pregnancies in spite of the existence of a large cyst which had developed ten years before, and was supposed to be in the mesentery. Eighteen months after the last childbirth, diarrhea suddenly appeared and the tumor rapidly diminished in size until it had completely disappeared. The retrospective diagnosis indicated a cyst in the pancreas which had finally emptied itself spontaneously into the intestines.

# A NEW METHOD OF DEALING WITH BOWEL PERFORATIONS COMMUNICATING WITH PELVIC ABSCESES.\*

THOMAS W. HUNTINGTON, M.D.

Professor of Surgery in the Medical Department of the University of California.

SAN FRANCISCO, CAL.

The problem of dealing with old bowel perforations in the presence of purulent collections in the pelvic area is fraught with many perplexities. I refer particularly to the fistulous communications between the bowel and tubal or tubo-ovarian abscess sacs. Such lesions present a twofold aspect: 1, as regards the immediate risk to the patient's life from general septic peritonitis; 2, as to the likelihood of establishing a permanent fecal fistula with its external outlet through Douglas' pouch or through the abdominal wound.

In this class of cases the visceral peritoneum, for several centimeters on either side of the perforation, has usually become thickened by a deposit of plastic material and has virtually lost its identity as a serous membrane. Immediate closure of a bowel perforation with such an environment by any of the suture methods, has in the majority of cases proven disappointing. The intestinal coats are so altered as to insure, in a majority of instances, reopening of the perforation before many hours have elapsed. On the other hand, experience has taught that a bowel resection at such a time is a most formidable if not hopeless undertaking. Two disastrous experiences in the past deeply impressed me with the necessity of devising a more rational method of dealing with such lesions.

It is a matter of general experience that a fecal fistula, where the bowel opening is closely approximated to the parietal peritoneum in the floor of an abdominal wound, tends to spontaneous closure without subsequent embarrassment. This idea is amply borne out by observing a large number of fecal fistulae associated with appendicular abscesses, which, as a rule, close without operative interference. This consideration has led me to what I believe to be a safe and surgical plan of procedure in such an emergency.

The following case admirably illustrates the plan which I had outlined and which will be definitely detailed below.

Mrs. H., age 35, has suffered for the past five or six years from pelvic cellulitis, with occasional acute attacks. These have become more and more frequent. For the past year she has suffered constantly. I saw her in consultation about Sept. 20, 1901. At that time she had become greatly emaciated; skin was dry and markedly pigmented; tongue was dry and furred. Temperature ranged from 99.5 degrees to 102; pulse 106. Bowels were constipated. Menstruation was irregular and painful.

Physical Examination: The abdomen was flat; the abdominal muscles on left side were rigid. A tumor was perceptible above the pelvic brim over the sigmoid flexure, irregular in outline and excessively tender under pressure. Slight tenderness existed over right tube and ovary. Uterus was fixed. Neither ovary nor tube could be outlined per vaginam.

Provisional Diagnosis: Left pyosalpinx with probable destruction of corresponding ovary. Laparotomy was advised and the operation was proceeded with on Sept. 22, 1901.

On median line incision, the right tube and ovary were found to be the seat of inflammatory trouble and were removed. On the left side a tubo-ovarian abscess was located high up in the pelvis. To the abscess wall the sigmoid flexure was firmly adherent for a distance of four or five inches.

Patient was placed in Trendelenburg's position. Abdominal contents were carefully isolated by gauze pads. The adherent colon was then carefully dissected from the abscess sac. During this procedure it was found that a communicating track existed between the abscess and the bowel. This had been temporarily closed, but as the bowel was separated there appeared an old perforation of the colon about one centimeter in diameter. At this juncture the abscess wall collapsed and pus escaped freely into the pelvic cavity. This was removed by careful sponging. The bowel perforation was temporarily closed by a purse-string suture. The abscess sac was dissected out and removed. Pelvic drainage was secured by vaginal route.

The ends of the suture used in closing the bowel perforation had been left uncut. To these I attached a small sponge pad for the purpose of identification. This was dropped into the pelvic cavity, and the median line incision closed. An anterior colostomy incision was then made over the sigmoid. Through this the buried sponge was recovered and the bowel perforation was drawn up into view. The bowel was then carefully sutured to the parietal peritoneum, thereby completing a formal colostomy. The median incision was sealed and a loose dressing applied to the lateral opening. Time of entire procedure was two hours. Time of second step was twenty-five minutes. Reaction was fairly prompt, and at the end of the third day the patient's condition was excellent. Median line incision healed without interruption. All fecal matter passed by artificial opening subsequent to operation. I had hoped that this would not be permanent, but owing to the sagging of the colon above the colostomy a spur was formed, closing the lumen of the bowel below the artificial opening. Temperature fell to the normal point; her appetite was regained and her general condition improved rapidly.

On October 23 her condition was such as to warrant an attempt at closure of the artificial opening. An elliptical incision was made encircling the artificial anus, the peritoneum being opened throughout. Through this the colon was drawn out and exposed for a distance of three inches above and below the perforation. About four inches of the colon was resected. An end-to-end anastomosis was accomplished by the Connell suture method. The abdominal wound was then closed by through-and-through sutures.

Time of operation was one hour and thirty minutes. The wound healed without incident. Rectal feeding was resorted to during the first three days, after which time liquid food was administered by the mouth. Bowels moved voluntarily on the fifth day and the patient left the hospital in perfect condition on the fourteenth day.

So far as I know the procedure in this case has never heretofore been suggested. While immediate closure of a bowel perforation in cases similar to the foregoing has within my knowledge and experience been occasionally accomplished, such fortunate result has not been the rule. While I have had no opportunity of carrying this investigation further, I am strongly of the opinion that the general plan pursued in this case

\* Read before the California Academy of Medicine, December 24, 1901.

will prove of value in dealing with a considerable number of complications involving fecal fistula. It was my original intention to have left the provisional purse-string suture undisturbed, thus placing the closed orifice of the perforation in the floor of the colostomy wound, with the hope that the patency of the colon lumen would have been re-established and rapid repair have been accomplished. During the manipulation, however, the provisional suture was torn out and an artificial anus was established at once.

Incidentally, I wish to express my high appreciation of the work done by F. Gregory Connell, bearing upon the matter of intestinal suture as described by him. (*THE JOURNAL A. M. A.*, Oct. 12, 1901.) I have thus far employed the Connell method in two cases with the utmost satisfaction. Its technique when once fully understood is simple and its various steps can be completed with a fair degree of rapidity. So far as safety is concerned, I believe it is capable of demonstration that the placing of the knot within the lumen of the bowel is a most important consideration.

### A CASE ILLUSTRATING PLASTIC SURGERY OF THE EYELIDS.

CASSIUS D. WESCOTT, M.D.

Assistant Professor of Ophthalmology at Rush Medical College;  
Assistant Ophthalmologist to the Presbyterian Hospital, etc.  
CHICAGO.

During my service at the Presbyterian Hospital in the summer of 1900, Miss Sarah McB., aged 38, presented

Fig. 1.—August 6. After first operation on cheek.

herself for the correction of deformities of the eyelids resulting from burns, which she had received six months before by falling into a grate fire in a fainting fit. As shown in photograph No. 1, the soft parts had suffered severely on both sides of her face, a portion of the right wing of the nose had been lost, and there was complete ectropion of the upper lid of the right eye and almost

complete eversion of the lower lid of the left eye. The brow just over the nose was so deeply burned that a portion of the external surface of the frontal bone had necrosed and come away during the dressing of the burns. The new skin which had formed in this region and over the right eye was extremely thin and poorly nourished, and the ciliary border of the lid was tightly

Fig. 2.—September. One month after operation for restoration of upper lid of the right eye.

drawn up and firmly adherent to the periosteum. In the left cheek was a very thick keloid scar, which sent an arm to the lower lid of the left eye, dragging it down and out and away from the globe. The cornea of the right eye was constantly exposed to dust and the danger of trauma and only an excessive flow of tears, which kept the epithelium moist and washed away the dust, saved it from inflammation, ulceration and the usual sequelæ.

As there was a broken-down and suppurating area over the right brow, it was not deemed advisable to begin work there, and the first operation consisted in the removal of the large scar of the left cheek and the restoration of the lower lid of the left eye to its normal position, by a free dissection and crowding up of the entire cheek. This was done July 6 and the immediate result was quite perfect; but, as so often occurs in plastic surgery in all parts of the body, a portion of our flap sloughed near the outer end of the lid and the final result was an ectropion almost as complete as there was in the beginning. The condition of the patient's heart and kidneys did not permit of another anesthesia until August 15, when I made a free dissection of the upper lid of the right eye, stitching it to the lower lid and bringing down a large flap from the forehead, with pedicle on the temple, to cover the extensive surface exposed. After this flap from the brow was carefully stitched in place, the area from which it was taken was filled in with Thiersch grafts, as shown in photograph No. 2, which was taken one month later. Healing after this operation was very satisfactory, and on October 6

the left lower lid was restored to its normal position by making a large V-shaped incision below and to the outer side and converting this V into a Y by freely dissecting and crowding the flap up, thus forcing the free edge of the lid into its proper position. Healing was slow, but the ultimate result has been good. Both eyes are closed during sleep and photograph No. 3 shows the patient's appearance one year after the operation on the right eye.

When all tenderness had disappeared from the scars, the patient was referred to Mr. Hugo Ad. Oldenborg for massage, and there is good reason to believe that his careful and systematic treatment was of great assistance in obtaining the excellent final result.

I am also indebted to Dr. A. I. Bouffleur for his valuable assistance in my operations, and for undertak-

to one side or the other within a range of five millimeters or even more, notwithstanding its frequent median position inferiorly; that the plane of the septum was roughly antero-posterior, passing between the anterior and posterior surfaces, but occasionally it might so deviate that one sinus would lie partly overlapping the other, even to an extent of 2 centimeters; that there were no absolutely certain guides by which the degree of development of the frontal sinus in the adult could be determined before attempting to expose it.

Previous to entering a frontal sinus some months since I secured three frontal bones and attempted to explore with my drill that sinus corresponding to the one on which I was to operate. I was amazed to find that No. 1 had almost no sinus on the left side; that the sinus on the left side of No. 2 extended not more than 3 milli-

Fig. 3.—September, 1901. One year after last operation.

ing the repair of the nose; the appearance of which he improved very much.

31 Washington Street.

## THE X-RAY IN DETERMINING THE LIMITS OF THE FRONTAL SINUS.

JOHN HAROLD PHILIP, M.D.

SAN FRANCISCO.

In the June number of the *Laryngoscope* I note the following from the pen of Dr. Jonathan Wright: "I have lately seen the frontal bone perforated and the dura mater wounded with disastrous results in a case in which the frontal sinus was lacking on that side."

Dr. Howard A. Lothrop, of Harvard University, after carefully examining 250 frontal sinuses, from dissecting room material, concluded that there was no external landmark defining the superior limit of the sinus; that the external angular process of the frontal bone was not often the limit of the sinus laterally; that in the majority of cases the septum (between the sinuses) deviated

meters beyond the median line and that there was no septum; there was no communication with the left nasal cavity. No. 3 seemed normal. One can not well overestimate the surgical importance of such anatomical anomalies, whose frequency is unquestioned.

As an aid to determining, previous to operation, the limitations of the frontal sinuses I suggest the x-ray.

The radiograph illustrating this article was taken for me by Mr. Cox of the San Francisco Polyclinic. Length of exposure was eight minutes; distance of tube from plate, 20 inches; plate over-developed and the print was sun-printed and overtoned. My patient's head lay obliquely on the plate and the affected sinus lay undermost. This explains the position of the canula, its tip extending apparently beyond the posterior wall of the sinus. For cosmetic reasons I entered the sinus from within the nasal cavity. (My patient was a young woman of 24.) Wishing to be certain that my canula was not in an anterior ethmoidal cell, I had a radio-

graph taken, when to my surprise I saw clearly defined the limits of my sinus.

Incidentally it may be of interest to note that the antrum on the left side served apparently as a reservoir for the pus coming from the corresponding frontal sinus and anterior ethmoidal cells. I removed the anterior one-third of the middle turbinate and irrigated the antrum through the ostium maxillare. After a few days' treatment the fluid used for irrigation was returned almost clear in the morning, but rather cloudy in the afternoon, although only one-third as much time had elapsed between the washings. I plugged with gauze the natural opening into the antrum and was rewarded by getting no evidence whatever of pus as long as it remained there. This proves, it would seem, that the antrum in question was not the seat of an inflammatory process. It only ceased discharging pus when it no longer gravitated into it from the anterior ethmoidal cells and frontal sinus, by way of the infundibulum. The right antrum was also involved; it was entered through the alveolar process and a tube left in for drainage.

## Clinical Report.

### TWO UNCOMMON CASES OF NASAL TUMORS.

RICHMOND MCKINNEY, M.D.

Laryngologist to East End Dispensary, and to Presbyterian Hospital.

MEMPHIS, TENN.

#### CYST OF INFERIOR BONY TURBINATE.

Alice S., of Grenada, Miss., colored, aged approximately between 30 and 35 years, a stout, apparently healthy woman, consulted me on Nov. 16, 1901, with the following history: She had had a fulness in the right nostril for some time, the exact date of its beginning being indefinite, but perhaps could be traced back several months. The condition occasioned no pain, only inconvenience. The growth in her nose had been incised on two different occasions, but according to her statement nothing other than a little blood followed each of these incisions. Examination revealed an enlargement of the anterior end of the inferior turbinated body. This growth was sessile and practically completely occluded the naris. On pressure with a probe, the swelling proved to be edematous. Under cocaine anesthesia the tumor was incised, and a thin, sero-purulent discharge, about a teaspoonful in quantity, followed the incision. The probe revealed that the bone underlying this cyst was uncovered and excavated, the interior of this cavity being roughened, showing that degeneration was going on. The cavity of the cyst was freely curetted, leaving a smooth bony surface. After curetting, a cautery point was passed freely around the inside of the cyst. Recovery was uninterrupted, and, although instructed to report a return of the growth, I have since heard nothing from the patient.

The literature of cysts of the nose is strangely lacking, yet this may be owing to the fact that they are considered conditions of some rarity. Still, I believe that simple retention cysts, not involving the bony framework of the nose, are much more frequent than is generally supposed; but cysts of the bony structure are no doubt very occasional in occurrence.

The origin of bony cysts of the nose is one of the many moot points in medicine, and I can add no theory to the many already advanced in accounting for the absorptive or necrosing process which produces these cavities in the nasal bones. Whether it be due to a "rarefying otitis," a "necrosing ethmoiditis," as described by Woakes, or to one of the numerous other processes as suggested by various investigators, must remain as yet unsettled.

In my case a question might be raised as to whether the process began within the bone and by an outward extending necrosis destroyed the periosteum overlying the spot of beginning degeneration and distended the mucous membrane at the

site of degeneration, or whether it began as a retention cyst of the mucous membrane and by an erosive process produced bony exfoliation at the base of the cyst. I am inclined to believe that the former was the course taken by the disease.

The majority of the cases of nasal cyst that have so far been reported have been located on the anterior end of the middle or inferior turbinated body, and most of the reported cases have occurred in females.

#### CYSTIC FIBROMA IN A BOY 12 YEARS OF AGE.

Ulysses C., of Eudora, Miss., aged 12 years, was referred to me by Dr. A. J. Emerson, Eudora. The boy had the following history: His nose has been stopped up on the right side for an indefinite period, and he suffers from profuse and frequent nose-bleed from this side. He has occasional attacks of tonsillitis, and his head and ears hurt a good deal. Examination discloses a reddish, polypoid tumor, about the size of a hazelnut, pedunculated and apparently springing from about the junction of the cribriform plate of the ethmoid with the anterior cartilaginous septum. The tumor was seized with a slender dressing forceps and twisted loose from its attachment. During the process of removal, the growth burst and discharged a dark, grumous, foul-smelling material, and hemorrhage was very free. After removal of the tumor, its site of implantation, which proved to be the cribriform plate, was cauterized with the electrocautery. Investigation of the histologic structure of the growth showed it to be a fibroma.

Nasal polyps of any kind are rarely seen at such an early age. Moure having found that in 10,520 cases of nasal polypi only five occurred in children; also the character and site of origin of this growth was such as to excite my interest. There was no question of the fibromatous structure of the tumor, although there was, as almost invariably is the case, some myxomatous tissue to be found in the sections examined, but hardly enough to warrant calling the growth a myxofibroma. It is claimed by some observers that nasal polyps are always edematous fibromata, and Jonathan Wright states that true myxomata are never found within the nasal chambers. Certainly the mucous polyps that I have from time to time removed in other patients have presented no such fibromatous structure formation as the case that I have just reported. Fibromata are, as in my case, usually found singly, which is hardly ever the case with myxomata. Another feature of interest in this case was the site of implantation of the pedicle, which was found to be the cribriform plate of the ethmoid, a most unusual source of origin of these growths, which commonly spring from the naso-pharynx or posterior end of the middle turbinate. This fact led me to seek for some traces of necrosing ethmoiditis which might account for the etiology of the tumor, but I could find no further indication of bony degeneration.

Still another uncommon feature of this growth was that it was pedunculated, as they are in most instances observed to be sessile, with a broad base.

Lyceum Building.

**Unbreakable Glass.**—The *Journal d'Hygiène* of February 25 publishes a description of the unbreakable glass made by compressing ordinary devitrified glass, and its advantages for clinics, hospitals, etc. It makes the best material for floors, wall coverings, ceilings, etc., as it is not affected by the copious use of water and disinfectants nor by the most powerful acids, nor by freezing. It is used extensively at Reverdin's polyclinic at Geneva and in establishments where acids are employed in manufacturing. Recent tests at the French Laboratory of Bridges and Highways proved that a force of 2023 kilograms to the square centimeter was required to crush it, while granite can be crushed with 650 kilograms. Tests with a rapidly revolving grindstone showed that it resisted wear better than Saint Raphael porphyry and other extremely durable stones. It also surpassed other materials used in floors and pavements in its resistance to weights falling on it.

## FERMENTS IN PATHOLOGY.

While the chemical constitution and physical properties of ferments as yet remain obscure, their importance in various biological processes is being disclosed with increasing emphasis by continued investigation. There is no sharp line of division between the nature of physiological and pathological processes and fermentations; recent investigations show that ferments may exercise just as important activities in pathology as in physiology. From the standpoint of physiology we may divide ferments into two great groups, as suggested by Jacoby in a recent review of the significance of ferments in pathology:<sup>1</sup> 1, the ferments in the secretions, which prepare the food for absorption, and 2, the intracellular ferments, which preside over the oxidizing and other cellular functions. Referring to digestive ferments, Jacoby cites the observations of Pawlow, showing the close dependence of the secretion of the gastric juice upon so-called reflex nervous influences, as corroborative of the old clinical experience that digestive and nervous disturbances are closely associated. Pawlow showed that stimulation of the appetite and other means may cause secretion of gastric juice without the presence of even a trace of food in the stomach. The inference that grave digestive disturbances may exist without any anatomical changes in the walls of the stomach lies near at hand; and the therapist immediately thinks of measures that may remove nervous disorders, the exact nature of which are not now clearly understood. If he chooses, the physician may cite the foregoing as an example of the anticipation by clinical observation of discoveries by more exact and more satisfactory scientific methods.

The self-digestion of tissues, or autolysis, shown by Salkowsky to depend on an intracellular ferment which is widely spread in the organism and to which more extended reference was made in these columns recently,<sup>2</sup> is claimed by Jacoby to be markedly increased in the liver of dogs in phosphorus poisoning and he suggests that the rapid and excessive destruction of hepatic parenchyma in acute yellow atrophy of the liver may depend upon a similar increase of a fermentative process that normally is held in rigid check. Among other and probably less obscure instances of tissue self-digestion may be mentioned the softening which occurs in purely

chemical suppuration, such, for instance, as Leber studied after inserting metallic copper in the anterior chamber of the eye of rabbits; the liquefaction of sterile, necrotic tissue, and of the huge solid exudations that form in the lungs in typical croupous or lobar pneumonia. Müller and Simon have shown that in the latter instance it concerns a genuine autolysis. When we recall that a lung may be freed in a few days from a mass of exudate, weighing several hundred grams, and this largely by absorption rather than by expectoration, we obtain some idea of the power in this case for good of the autolytic ferment or ferments. Whether the self-digestion or pneumonic resolution is due to increased activity of the ferments normally present or to immigration of ferments from other sources has not been determined. Leucocytes are generally thought to contain digestive ferments and they may play an important rôle in the lung in resolution.

The discovery in animal tissues by v. Fürth and Schneider of tyrosinase, an oxidizing ferment that produces pigments somewhat similar to the melanin of melanotic tumors,<sup>3</sup> has awakened the hope that possibly in this direction may be found the much-needed explanation of the production of melanin pigment in these tumors, often in such quantities as to lead to melanemia and melanuria. Should this hope be realized, it would become an exceedingly interesting and important problem to determine the exact relationship between the ferment and the multiplication of the tumor cells, but speculations of this kind, tempting as it is to indulge in them, are not yet warranted.

The reversibility of ferments—demonstrated by Hill in the case of maltase; by Kastle and Loevenhart for lipase, the fat-splitting ferment; and quickly suggested as probably true for other ferments also—has been applied by H. G. Wells<sup>4</sup> in an interesting manner to the explanation of various pathologic processes, more particularly those in which disturbances of the normal metabolism of fat are at work. These necessarily fragmentary references to the rapidly accumulating knowledge concerning ferment actions may serve to indicate the new light in which various pathologic processes appear when studied from the side of the forces at work in them. No doubt this branch of experimental pathology in the future will add also to our means of combat and control of diseases.

## POISONING IN HISTORY.

Every now and then there is a revival of stories of the famous poisoners of history. We are told of wonderful drugs that accomplished their fell purposes with timeliness and dispatch, yet without leaving any undesirable trace behind them by which the possessors of the secret might be rendered amenable to the law. An article on "Champion Poisoners" in the current number

1. Centralbl. f. Path., Jan. 2, 1902, xiii, 2-8.

2. THE JOURNAL A. M. A., Dec. 7, 1901, 1536.

3. THE JOURNAL A. M. A., Dec. 14, 1901, 1612.

4. THE JOURNAL A. M. A., Jan. 25, 1902, 220.

of a popular magazine<sup>1</sup> is a fair sample of these quasi-historical collections of marvelous facts. There is the story of the wonderful poison rings found at Pompeii, whose touch to food or drink, it is fabled, was sufficient to cause death. The artistic poisoning methods are dwelt on most. There is the preparation of arsenic—tasteless, colorless, odorless—that might be smeared on one side of a knife with which a peach was cut, the poisoned half being given to the victim while the murderer could eat the other half with impunity. Then we are told the story of the drinking cup that turned wine into venom, and last of all the looking glass with the magical but at times accommodating power of killing anyone who looked into it. This last is too much for the veracious essayist, who says that modern science has denied the possibility of any such murderous influence, though of course modern science is very skeptical and has spoiled many a good story.

It may be said, however, that most of the stories of wonderful secret poisons are quite as incredible as that of the magical mirror: Poisons whose action could be timed to a nicety; poisons whose evil influence would be exerted not immediately, but after months or even years; poisons that left no trace; all these are popular traditions but with no substantiation in veridical history. Long ago Cicero said: *omne ignotum pro magnifico*, "what is unknown is always held to be great": the maxim is especially true of the legends of poisoners and their occult powers, as they are found in traditional folklore. Fear embroidered all manner of details on the actual facts in cases of unexplained death. It was to the interest of those who pretended to deal in poisons, especially for criminal purposes, to magnify the wonder-working qualities of their remedies. Their credulous customers could make no public reclainer if the drugs failed to accomplish their purpose. Like the vendors of the wonderful drugs that in our day are sold so commonly to produce abortion or enlarge the bust, the presumed poisoners of former generations had little to fear from legal prosecution if their recipes proved unavailing. Accidental coincidence probably at times intervened to confirm the poisoners' hopes as it does in our own day to give a reputation for efficiency to patent medicines. It is not improbable that the supposed poisons of medieval times were, as a rule, as harmless in their effects as the vaunted abortifacients that cure all female irregularities, or, for that matter, any of the other patent medicines of our twentieth century.

The detailed knowledge of toxicology required in many of the stories of wonderful poisons was not possessed and could not be obtained in former times. The ancients knew hemlock, opium, arsenic, aconite and mandrake, but scarcely more. All of these poisons are rather easily recognized in their effects and none of them are easily taken in any considerable quantity without their taste or odor being suspected. It requires long and careful animal experimentation with exact prepara-

tions and not with crude drugs to determine the slow effects of poisoning. This is the sort of knowledge they could not have had in former times. It is improbable that any great secrets were lost. Modern pharmaceutical research has tried all the usual substances that the ancients knew or even mentioned casually and we are thoroughly aware of their properties. There are among them no drugs that would kill in the minute quantities often supposed to be administered in the old stories. There are no tasteless powders that could be shaken on victuals like a pinch of salt, and yet surely cause death. Such stories are like the fairy tales, for advertising purposes, of the remedy that put in coffee cures the tobacco or the drink habit, without the victim's knowledge.

There are many things besides poisoning which explain the sudden and unaccountable deaths of great people in history. Our modern appendicitis furnishes from one point of view a typical case of poisoning. The victim, usually strong and healthy, is taken a few hours after a meal with a severe pain in the abdomen, and dies in twenty-four to forty-eight hours. In women there is the added possibility of fatal extra-uterine pregnancy and there are many other pathologic conditions that could well masquerade as poisoning cases. The death of Germanicus, hinted at by Tacitus as due to poison at the hands of Tiberius, who was jealous of his success in arms, seems really to have been due to an acute exacerbation of an old tubercular process relighted up by the disappointment of losing his command. There seems good reason to think that some time when history is rewritten from the standpoint of the trained pathologist we shall hear much less of poisoning cases in history than we do at present.

#### FORMALIN IN TUBERCULOSIS.

In the report of the meetings of the British Congress on Tuberculosis,<sup>1</sup> held in London in July, 1901, Maguire of London detailed the results of over 100 cases treated by him by means of intravenous injections of formalin as well as of numerous cases treated by other observers. Cases treated in the early stage all showed disappearance of physical signs and of bacilli. In cases with cavities the signs of active disease disappeared and the bacilli also. In a recent note,<sup>2</sup> Maguire states that the treatment by intravenous injections of formalin is on trial, and as yet its results do not warrant any authoritative opinion, still less any positive statements as to its being a "cure for consumption."

Fischer and Ticken<sup>3</sup> have made some observations which appear to have direct bearing upon the use of formalin in the treatment of human tuberculosis. Their experiments had to do with 21 guinea-pigs which had been inoculated with tubercle bacilli by the intraperi-

1. British Medical Journal, Aug. 3, 1901, 319.

2. British Medical Journal, Feb. 15, 1902, 428.

3. Transactions of the Chicago Pathological Society, Feb. 10, 1902, 61.

toneal injection of a suspension of a culture from spuntum. The animals were divided into four groups of six each, being grouped together according to weight. The heaviest one of each group was reserved as a control. The other animals received intraperitoneal injections of dilute solutions of formalin (8 c.c. of 1 to 1000) at intervals of one or two days. The control animals, which received no injections of formalin, lived longer and fared better than those which were treated. At the postmortem examination, the animals which had received injections of tubercle bacilli followed by those of formalin solutions, always presented the same picture. The changes were most severe in the lungs and liver, which organs were often nothing but masses of friable caseated material. There was extensive involvement of the entire system of lymphatic glands. Histologically there were the usual appearances of tuberculosis together with such degenerative effects as had been previously shown by Fischer to accompany the injection of formalin. In the animals which had received injections of formalin the tuberculous foci were diffuse, seemed to break down more rapidly and were not accompanied by as marked an inflammatory reaction as was the case in the tuberculous animals not injected with formalin. The experiments show conclusively that in guinea-pigs the intraperitoneal injection of dilute formalin has an unfavorable action upon the tubercular process. The authors conclude that the development of miliary tubercles in spots that were actually bathed in dilute formalin lead them to believe that it takes a much stronger solution of formalin to bring about the destruction of tubercle bacilli than is commensurate with life.

In view of these facts it does not seem at all probable that small amounts of formalin injected into tuberculous patients can have any deleterious influence upon the tubercle bacilli. It would seem that tuberculous patients had been subjected to the action of enough antiseptics, poisons, etc., with apparent improvement for a time, to have shown that other factors than the remedy are very largely responsible for the results. Before resorting to the injection of active chemical agents into the tissues and blood of this unfortunate class of patients, it would be advisable to first demonstrate in experimental animals that very definite benefit could reasonably be expected to follow.

#### TETANUS AFTER VACCINATION.

The recent accidents of tetanus after vaccination in Camden, N. J., amounting as they did almost to a limited epidemic, have left some questions rather unsatisfactorily answered. We can be reasonably certain that the vaccine lymph itself was free from germs and therefore innocent to that extent and also that there must have been an unusually general dissemination of the tetanus infection. But just why so many subjects of vaccination should thus suffer, when other traumatism were only rarely affected, is a question that disturbs the laity and helps the antivaccination cause. It

is not a pleasant suggestion that the organism, or whatever it is, of vaccine is a specially favorable adjuvant to the toxic action of Nicolaier's bacillus, but nevertheless that is one of the possible inferences to be drawn from these recent occurrences. A rather interesting and suggestive paper on post-vaccination tetanus is contributed by Drs. W. and J. W. Findlay<sup>1</sup> in which they report a case in a woman and review the available literature. The authors conclude that in this case the source of infection was in the patient's skin, that its presence there—the vaccination having been made on the leg—was favored by the long skirts worn, which can hardly fail to favor infection when sweeping along our city pavements with the dusty covering of powdered soil, horse dung, etc. This seems probable enough, but they go on to say that the peculiar method of production and treatment of the vaccination wound would also favor the development of the infection. A surgical operation could probably have been performed with impunity on the same leg without any additional antiseptic precautions, "for the clean incision of the surgeon's knife militates against the very conditions which the vaccinator's lancet offers." Then, the sealing up of the wound furnishes the conditions required for an anaërobic germ to do its dirty work, and they also suggest that the vaccine itself may supply the accessory conditions required by the tetanus bacillus for the development of its toxin and the infection of the system.

It is a noteworthy fact that out of ten cases found in the literature by the authors, six and possibly seven were from the United States, and two others from Cuba, only one having been reported from Great Britain. This does not include the late Camden epidemic or other cases recently reported in this country; in regard to the Camden epidemic, which is mentioned in an addendum, the Drs. Findlay do not accept the conclusions of the local board of health as to the atmospheric infection. They ask: "Is it sound reasoning to conclude that because one of the many injured and wounded persons developed tetanus during the same period that several cases of tetanus were occurring after vaccination, that the tetanus germs must have been in the air? Of course, the tetanus germs were in the air—they are always there more or less—but is not the logical conclusion to be derived from these facts what we have already stated—viz., that the vaccination wound offers special facilities for growth to the tetanus bacillus? If atmospheric and telluric conditions alone were to blame, vaccination would not have claimed cases while injuries claimed but one case." In their own case the wound was throughout protected from the air, the scab was not even removed until after the tetanus had developed.

The legitimate deduction from all this is that we should not confine our attention too exclusively to any one cause. Air infection, skin infection, and every

1. London Lancet, Feb. 22, 1902, p. 506.

other possible source of germs or toxins should be considered and vaccination be conducted under as careful asepsis as a capital operation. The occurrence of such an epidemic, so to speak, as that at Camden shows what the possibilities of the concentration of tetanus germs may be, though the rarity of such is consoling. Millions have been vaccinated every year and yet the cases of tetanus following, so far as known in medical literature, could almost be counted on the ten fingers up to the past year. The danger is infinitesimal; but the fact that it exists should insure all reasonable precautions against it. It may be also true, as suggested above, that we err sometimes in a too rigid sealing up of vaccination lesions and thus favor elaboration of the toxins of possibly existing anaërobic germs.

---

#### DR. CHRISTIAN FENGER.

The death of Dr. Christian Fenger, which was noticed in our last week's issue, is a distinct loss to the profession and to medical science. There are few if any medical men who have come to this country from abroad who have earned a higher place in the estimation of their native-born colleagues. This was due not only to his rare scientific ability, but also to his personal qualities of unswerving honesty and truthfulness in all matters and his thoroughly ethical traits, professionally and otherwise. His personality was an attractive one; though brusque sometimes in manner he was always a gentleman, and his good qualities grew upon one on acquaintance. No man had warmer friends or fewer enemies. Of his scientific work it is hardly necessary to speak here; what he has done for scientific medicine in Chicago was reviewed editorially in the pages of *THE JOURNAL* in connection with the testimonial presented him by the profession a little over a year ago. We can only repeat what was then said, that "for years he has been the recognized type of the scientific surgeon and teacher." Modest and never assertive, all he said carried authority, the more so since all recognized that he himself would be the first to detect and acknowledge an error. His work lives after him and his record is a lasting and enviable one.

---

#### ENGLISH VIEW OF DEATH FROM BOXING.

The verdict of an English coroner's jury of "death by misadventure," in the case of a man killed in a fist fight, is commended by the London *Lancet*. It says: "It is for the pistol, the knife, and the attack by an organized gang as modes of settling quarrels between men or boys that the criminal law should be set in motion." This is giving a decidedly local color to a medicolegal opinion, and the dictum is about as justifiable as those in favor of dueling or lynch law. The fist may be very easily a fatal weapon, and those who are ready to use it on little provocation should not feel absolved from the full responsibility for whatever result may occur. The fist is supposed to be the natural British weapon for righting personal wrongs and has, therefore, a prejudice in its favor, which is, we think, indicated in the words of the editorial quoted. It is also the weapon of

the common bully and the most unchivalrous one of all, for it exaggerates the efficiency of mere brute strength. The only thing that can be said in its favor is that it is less surely deadly than most other weapons, but it can be deadly enough as has been time and again demonstrated. A duel with British fists, it is safe to say, is far more risky than the average French duel with swords, as regards injury and probably but little less so as regards life. The coroner's verdict may have been influenced by the special facts in the case, that the victim was the aggressor, etc., but the general condonation of murder by fisticuffs, in our esteemed contemporary, seems to us altogether without excuse.

---

#### THE ABSENCE OF THE FRONTAL SINUS.

The article in this issue by Dr. Philip on the use of "The X-ray in Determining the Limits of the Frontal Sinus" is a contribution to a subject that apparently needs more elucidation. The possibility of there being no frontal sinus at all in the adult seems not to have been always duly emphasized, as witness two recent articles in a leading medical journal that discuss operations in this region. In one of the two its occasional absence on one side is merely mentioned, in the other this possibility seems to have been entirely neglected. In 240 European crania Logan Turner<sup>1</sup> found one or both sinuses absent in 41, or 17 per cent., and both were absent in 18 of these, or 7.5 per cent., of the whole number. The great majority of these instances were in British skulls, but a still larger proportion of these anomalies is indicated in certain other races, notably the Australians, in 30 per cent. of whom both sinuses were wanting. The clinical importance of the condition and the desirability of any means whereby a more accurate knowledge of their existence can be obtained, are obvious. It is not always possible to accurately diagnose the affections of the region, or perhaps one would better say that mistakes in diagnosis are possible. Such a mistake would be all the more unfortunate if it led to an operation for opening a cavity that did not exist with the risk of wounding the dura or injuring the brain. Yet this appears to be possible in an appreciable percentage of cases.

---

#### PROPOSED INSPECTION OF SURGICAL OPERATIONS BY THE LAITY.

A New York legislator has introduced a bill requiring that in any operation on a woman in any hospital, medical college or elsewhere there must be in attendance three of her nearest relatives, who must remain with her until she is returned to bed. There must be absolutely no exposure other than is necessary for the operation, and the attendance of the relatives, it may be presumed, is to enable them to make any protests or criticisms they may feel called upon to utter if any detail of the operation shocks their sensibilities; it would be interesting to see how such a law would work. There are a number of embarrassing contingencies probable as regards its execution; the attendance of relatives will in many cases be difficult to secure, and the question arises whether the operation will have to be suspended

1. *The Accessory Sinuses of the Nose*, New York, 1902, p. 77.

in case one of them should lose his or her nerve and have to retire; the interference of a hysterical relative is another possibility to be considered. On the whole, it looks as if the enforcement of such a law would work badly for the patient and lead to serious suffering and even sacrifice of life. In fact, the law would of necessity have to be disregarded as soon as passed and would be one of the useless and ridiculous encumbrances on the statute books, but with the possibility of its being utilized for blackmail and annoyance. Its introduction is probably a bit of political shyster practice, but, in any event, the record of the New York legislature in regard to medical humbugs is fortunately such that it is hardly likely to become a law.

#### THE HOSPITAL QUESTION.

In this issue we publish a contribution discussing one of the leading questions of the day, but one that has not duly occupied the attention of the medical profession, viz., the relation of hospitals and hospital workers and administrators to the general practitioner. The hospital movement, as we may call it, is a fact to be met and the question is: Are we influencing its adjustment to the best interests of all as we should or are we allowing it to follow its own haphazard way? The subjects of inquiry suggested by Dr. Niles are pertinent ones and of special interest as regards the future of our profession. The so-called hospitals of the present, as of the past, include not only the public but the private institutions and the relation of each of these to general medical practice is a special problem of itself. The abuse of public charities in the one and the too frequent exclusive use for private emolument of the other are matters that will naturally suggest themselves and the ethics of hospital practice generally. Hospital positions are often sought by physicians and surgeons not exactly for their health, as the saying is, but as an indirect and sometimes a direct commercial advantage. The ever-pervasive commercial spirit of the day prevails to a greater or less extent in these institutions under the mantle of charity and science. The medical profession outside of hospital staffs is too often a sufferer from this cause. This is only one feature of the case to be considered, but to amplify upon all the points suggested by Dr. Niles would require more space than can be given. The ideal hospitals of the future will give all the advantages without the drawbacks of the present system; they will be open to the profession generally, while affording special scope for those whose acquirements make their services in demand for particular lines of work. Their multiplication under such conditions will be a distinct advantage to the public and the profession.

**THE NEW SWEDISH PHARMACOPEIA.**—After seven years of toil, the committee in charge of the revision of the pharmacopeia in Sweden completed its task and the new edition was ready January 1, 1902. It is entirely in Swedish except that the Latin names of the drugs are appended. It contains a department devoted to veterinarian drugs, and tables of maximum doses not only for man but for various domestic animals.

## Medical News.

### CONNECTICUT.

**Change in Medical Course.**—Yale Medical School has announced that the first year's studies can hereafter be arranged to be taken in the academic department, the second, third and fourth years being spent in the medical school proper.

**To Restrict Consumption.**—The Bridgeport Medical Association has voted to appoint a committee of five to confer with Health Officer Hill for the purpose of drafting an ordinance to be presented to the common council to restrict the spreading of consumption.

**Dr. Lindsley's Semi-Centenary.**—A complimentary banquet was tendered, February 20, to Dr. Charles A. Lindsley, New Haven, secretary of the State Board of Health, and emeritus professor of principles and practice of medicine in Yale Medical School, on the occasion of the fiftieth anniversary of his entrance to practice in New Haven. Dr. William H. Carmall acted as toastmaster.

**Indebtedness Wiped Out.**—Early in February the officials of the Hartford hospital appealed for funds to pay the debts of the institution, amounting to \$74,800. Before the end of the month the entire amount had been subscribed, with \$90 to spare, and in addition \$5000 has been added to the permanent fund. J. P. Morgan contributed \$25,000, subject to the raising of the remainder within a stated time.

**Mortality Reports.**—By reports received, there were 1124 deaths during the month of February. This was 48 less than in January, and 257 less than in February of last year, and 76 less than the average number of deaths in February for the five years preceding. The death rate was 14.9 for the large towns, for the small towns 14.6, and for the whole state 14.8. The deaths reported from infectious diseases were 194, being 17.2 per cent. of the total mortality.

### DISTRICT OF COLUMBIA.

**Health of the District.**—The report of the health officer for the week ended March 8, shows the total number of deaths to have been 106, of which number 96 were white and 37 colored; 132 births were reported, of which 76 were white and 56 colored, 65 male and 67 female. At the close of the week there were 11 cases of smallpox, 16 of diphtheria, 35 of scarlet fever, and 33 cases of typhoid fever under treatment. Typhoid fever is now being reported to the health department in accordance with the recent law approved February 4. With the view of lessening the transmission of tuberculosis in the District, the health officer has issued a very excellent monograph on the subject, which is being distributed free to the physicians and public. It goes thoroughly into the cause and nature of the disease, methods of transmission, disinfection and hygiene of the malady.

**Medical Practice Act Sustained.**—The Attorney for the District has sent the following reply to a physician of Virginia who desired to practice medicine in the District of Columbia without taking the necessary examination: He says the Secretary of the Board of Medical Supervisors has correctly followed the law in declining the requests. "It appears that the State of Virginia does not issue licenses to practice medicine to licentiates of the District of Columbia upon the conditions specified in the act of Congress. It therefore follows that licentiates of the State of Virginia are not entitled to practice medicine in the District until the license is issued by the Board of Medical Supervisors. It is requested in this case that a temporary license shall be issued pending the examination of the Board. I am of the opinion that the law does not authorize this, and that, therefore, the Board is without authority to issue a temporary license."

**Local Sanitary Laws.**—The local laws of the district governing contagious and infectious diseases and vaccination are quite efficient and satisfactory and fortunately give sufficient authority to the Commissioner and health officer to enforce the same. The present management of contagious diseases in the District has been brought to a high standard of efficiency and effectiveness by the present health officer, Dr. W. C. Woodward. The following sections of the laws are of interest:

**Authority of Commissioners:** Sec. 5. That whenever it comes to the knowledge of said health officer, either by the certificate hereinbefore provided for or otherwise, that any person in said District is suffering from any contagious disease said health officer shall cause one or more suitable placards or warning signs to be placed at once in a conspicuous position or positions upon, at or near the front entrance or entrances to the premises in which such person is, so that the same can be distinctly seen by passers-

by; said placards or signs shall contain, printed thereon in large letters, the name of the disease from which said person is suffering, and in small letters a statement of the law in reference to entrance to and exit from such house, and in reference to interfering with such placard or warning sign; if such premises be a hospital, asylum, hotel or apartment house said placard or warning sign may, in the discretion of said health officer, be placed in a conspicuous position within said premises, at such place or places as said health officer may determine, said placards or warning signs shall be displayed as aforesaid until such premises and the contents thereof are disinfected to the satisfaction of the said health officer, as certified by him, and for such time thereafter as may be necessary to demonstrate the freedom of occupants of said premises from contagious disease, namely in the case of cholera and yellow fever, 5 days; typhus fever, 21 days; smallpox, 16 days; the plague, 14 days; the glanders, 21 days: Provided, that in addition or in lieu of the placards or warning signs provided for above, said health officer may station a watchman or watchmen at such building or premises for the purpose of securing compliance with the provisions of this act.

**Provision for Quarantine:** Sec. 10. That no person in said District suffering from any contagious disease, or residing either permanently or temporarily in any building where there is such disease (or, if such building be a hospital, asylum, hotel or apartment house in the apartments where there is such a disease) shall leave such building or apartment, except with a written permit from said health officer, and then only in accordance with the terms of said permit; or with a certificate from said health officer certifying that such person can leave said building or apartments without danger to public health.

Sec. 21. That whenever any person in said District is an inmate of any premises occupied by three or more families, or of any tenement house, boarding house, lodging house, hotel or apartment house, and is suffering from any contagious disease, and can not in the opinion of said health officer, be properly isolated in such premises, tenement house, lodging house, hotel or apartment house, said person shall be removed as expeditiously as possible under direction of said health officer, to the public hospital or to such other place, satisfactory to said health officer, provided by and at the expense of said person, his parents or guardians; if such person can not, in the opinion of said health officer, be removed as aforesaid without endangering his life, said health officer may cause such persons in the vicinity to be removed as are in danger of contracting the disease. Any person suffering from any contagious disease, and requiring to be treated at public expense, may, at the discretion of said health officer, be removed to the public hospital for treatment.

**For Vaccination:** Sec. 23. That every person in said District having been exposed to the infection of smallpox (including varioloid) shall be at once successfully vaccinated, or vaccinated a sufficient number of times to make it evident that successful vaccination is impossible.

Sec. 24. That it shall be the duty of every person in said District to be successfully vaccinated a sufficient number of times to make it evident that successful vaccination is impossible, whenever the Commissioners of said District shall, by proclamation, declare such action on the part of every person, within a reasonable time, to be stated in said proclamation, necessary for public health. Provided, That this section shall not apply to persons who prove to the satisfaction of said health officer that they have been successfully vaccinated, or repeatedly vaccinated, as aforesaid, within five years from the date of said proclamation, or that they have had smallpox or varioloid.

Sec. 25. That the Commissioners of said District be, and they are hereby, authorized and empowered whenever said District is, in their judgment, threatened or afflicted with any contagious disease to cause house-to-house inspections to be made, to require, especially, the cleansing and disinfection of premises, or parts of premises, to provide accommodations for such persons as may be threatened by or afflicted with any of the diseases aforesaid, to provide gratuitous vaccination and distribution of disinfectants and to do or cause to be done such other acts not contrary to law as may be necessary in their judgment, to prevent the introduction or spread in said District of any disease aforesaid.

## GEORGIA.

**Dr. Long's Memory Honored.**—Georgia has chosen Dr. Crawford W. Long, one of the reputed discoverers of anesthesia, as one of the two subjects for statutes in Statuary Hall in the Capitol at Washington.

**Commencement of Medical College of Georgia.**—Lectures at this institution closed March 12, and on the following day the final examinations commenced. The commencement exercises will be held at the Opera House, Augusta, April 1. Chancellor Walter B. Hill of the State University will present the diplomas, and Dr. Theodore E. Oertel will deliver the address to the graduating class.

**Change in Editor.**—Dr. William E. Fitch, founder, and for many years editor and business manager of the *Georgia Journal of Medicine and Surgery*, Savannah, has sold his interest in the publication to his former associate and co-editor, Dr. St. Joseph B. Graham, who becomes editor and sole proprietor. Dr. Fitch will devote his entire attention to the practice of his profession in Savannah.

**Personal.**—Dr. Robert C. Eve, Augusta, assistant surgeon in the army, has left for his post of duty in the Philippines. Dr. H. C. Wood, Irwinton, has located in Dublin. Dr. Eugene Foster, Augusta, has been elected president of the local board of health. Dr. Hunter P. Cooper, Atlanta, has been appointed division surgeon of the Nashville, Chattanooga and St. Louis Railway, with headquarters at Atlanta, vice Dr. William P. Nicolson.

## ILLINOIS.

**More Patients at Bartonville.**—The Board of Asylum Commissioners has completed arrangements to receive 300 more patients at the Illinois Hospital for the Incurable Insane at Bartonville, near Peoria.

**Fifty Years of Practice.**—Dr. David Ellis, Augusta, who was graduated from the University of Louisville in 1852, has been in active practice in Augusta for half a century. He is now 76 years old and enjoys good health.

**St. Anthony's Hospital Staff.**—At the annual meeting of the medical and surgical staff of St. Anthony's Hospital, Rock Island, Dr. George L. Eyster was elected president; Dr. Joseph R. Hollowbush, vice-president, and Dr. St. Elmo M. Sala, secretary-treasurer.

## Chicago.

**Dr. John R. Neely**, medical director of the county institutions at Dunning, has gone east for a trip of ten days to inspect state institutions.

**Dr. Fenger's Estate.**—The will of Dr. Fenger, probated, March 18, provides for the disposition of an estate of \$110,000, of which \$100,000 is personal property. Mrs. Fenger is made executrix without bonds.

**Special Train to the Meeting of the American Medical Association at Saratoga Springs.**—The Chicago Medical Society has arranged with the Lake Shore and Michigan Southern Railway for a special train to Saratoga Springs, N. Y., to the annual meeting, June 16 to 13.

**Personal.**—Dr. Henry F. Lewis has gone abroad for the summer. Dr. Alfred Helton has secured an internship at St. Mark's Hospital, Salt Lake City, Utah. Dr. Albert G. Huizinga, employed as disinfecter and fumigator by the Department of Health, has resigned. Dr. George W. Boice has located in Rushville.

**Translated into Spanish.**—Dr. N. Senn's book on the Spanish-American war, most of the matter of which appeared in *THE JOURNAL*, has been translated into Spanish by Dr. Juan Redondo of Madrid, a surgeon of high rank. The illustrations which appeared in the original volume have not been incorporated in the Spanish edition.

**New Hospital Opened.**—Formal opening exercises at the new St. Mary's of Nazareth Hospital, Leavitt Street, near Division, were held March 16. The hospital is a five-story fire-proof building and occupies an entire block. The building will be in charge of the Sisters of the Holy Family of Nazareth, and the medical staff of ten physicians will be in charge of Dr. A. J. Ochsner.

**Communicable Diseases of Children.**—The contagious diseases of childhood continue to be unusually prevalent; scarlet fever especially is endemic in many parts of the city, and, together with measles and whooping cough, is of a severe type, with a high mortality rate. There were 29 deaths from the four principal communicable diseases of the young reported to the Department of Health, last week, as against only 14 in the corresponding week of last year.

**The Week's Mortality.**—Although there were forty more deaths from all causes reported last week than during the week previous and 11 more than in the corresponding week of 1901, the rate is still well within the average March figure. During the twenty years, 1882-1901 inclusive, the average rate was 18.40—the month being ninth in the mortality scale, November having the lowest and July the highest average death rate. Last week's rate was 15.86 per 1000 per annum.

**In Memory of Dr. Fenger.**—The Elgin Physicians' Club held a special meeting, March 8, forwarded a telegram of condolence to Mrs. Fenger and voted to draft a set of resolutions to be presented to Dr. Fenger's family. The Chicago Medical Society met March 12, but immediately adjourned. The following resolutions were adopted by the Medical Staff of the Evanston Hospital on the death of Dr. Christian Fenger:

The members of the staff of the Evanston Hospital hereby express and record, the sense of their loss in the death of their colleague, Dr. Christian Fenger, who has passed from faithful service to well-earned rest.

*Resolved*, That in the death of Dr. Fenger, the hospital loses one of its ablest counselors and most brilliant surgeons. For his distinguished services in pathology and surgical science he was knighted by an appreciative king, and honored by the profession of two continents.

The works of our eminent associate are his grandest memorial, and their influence the fittest benediction. We do not attempt to measure the ennobling effect of such a life, nor fathom the far-reaching power of such enlightened service as his to mankind, but would simply offer this expression of his worth, that, as a testimonial, it may be entered upon the minutes of the Evanston Hospital Association, and extended to his family as a mark of our sympathy and esteem.

## INDIANA.

**Kokomo City Hospital.**—The Kokomo City Hospital Association was incorporated March 10 with a capital stock of \$15,000.

**Endowment for Epworth Hospital.**—The family of the late Hon. Clem Studebaker have offered an endowment fund to Epworth Hospital, South Bend, provided the institution first be freed from its present indebtedness of \$50,000.

**Hammond Hospital Staff.**—The medical staff of St. Margaret's Hospital, Hammond, has re-elected the following officers: Dr. James T. Clark, president; Dr. Cyrus W. Campbell, vice-president, and Dr. H. Edgar Sharrer, secretary.

**Doctors Win Suit.**—The suit of Mrs. Julia Varnes, Tipton, against Drs. George H. F. House, Indianapolis, and J. K. Bates, Broad Ripple, for malpractice, was decided in favor of the defendants, by a Hamilton County jury, March 6.

**Diverticulum for Appendix.**—In the Whitley Circuit Court, March 6, Edward Zumbrum was given damages of \$1500 in his suit for \$5000 against Drs. James W. Squires, Churubusco, and Nathan B. Moore, Merriam. The plaintiff charged that the defendants operated on him "for appendicitis and, instead of removing the vermiform appendix, they cut off the diverticulum, which is a growth on the intestine similar to the appendix."

**Diseases.**—The monthly reports to the State Board of Health show that smallpox was the most prevalent disease in February, and pneumonia the second most prevalent. Pneumonia was fifth in January, bronchitis being second that month. The order of disease prevalence in February was: Smallpox, pneumonia, bronchitis, influenza, rheumatism, tonsillitis, pleuritis, measles, scarlet fever, diarrhea, typhoid fever, diphtheria, erysipelas, whooping cough, puerperal fever, cerebrospinal meningitis, cholera morbus and cholera infantum.

**Deaths.**—The February deaths numbered 2874, rate per 1000, 14.8. In the same month last year there were 3350 deaths, rate per 1000, 17.3. This was therefore, in this comparison, a reduction of 476 in the number of deaths and 2.5 in the rate; 14.6 per cent., or 395, of the total deaths were infants under one year of age and 29.3 per cent., or 792, were 65 and over. Pneumonia heads the list with 512 deaths, and other important causes of death come in the following order: Consumption 337, violence 119, diphtheria 26, cerebrospinal meningitis 21, scarlet fever 19, diarrheal diseases 13, whooping cough 12.

## KENTUCKY.

**Dr. Stone's Estate.**—The estate of the late Dr. Barton W. Stone, Louisville, is valued at nearly \$35,000.

**Accidents.**—Dr. William T. Durrett, Louisville, slipped and fell, March 6, breaking his right leg below the knee.—Dr. James M. Young, Bloomfield, fell on the ice and fractured his hip.

**Pest-house Dynamited.**—Unknown persons evinced their disapproval of the construction of a smallpox isolation hospital near Burgin, by blowing the building to pieces with dynamite, March 9.

**Dr. Thomas P. Satterwhite,** Louisville, has been elected President of the Board of Commissioners of the Central Lunatic Asylum at Lakeland for the eighth successive time. Dr. Satterwhite was one of the advocates of the Carroll law recently defeated in the legislature, which provided for the placing of the asylums under a central board of control.

**Milk Adulteration Laws.**—Dr. Allen, Louisville, will endeavor to enforce the laws regarding the adulteration of milk, beginning with March 15. His department is now equipped with complete chemical and bacteriological outfits, with competent men in charge of these departments, and the profession expect much good to result from his efforts. Adulterated milk is defined as that containing more than 88 per cent. of water or fluids; containing less than 12 per cent. of milk solids; less than 3 per cent. of fat or having a specific gravity of less than 1.020; milk drawn from animals within ten days before or ten days after parturition; milk drawn from animals fed on distillery waste; from cows kept in a crowded condition; milk from which any part of the cream has been drawn. Cream sold as such shall contain 20 per cent. of butter fat.

## MARYLAND.

## Baltimore.

**Half a Century.**—Dr. Robert H. Goldsmith, Baltimore, celebrated the fiftieth anniversary of his graduation from the University of Maryland School of Medicine, March 9.

**Fraternity Banquet.**—The fourth annual banquet of Alpha Chapter, Phi Chi Southern Medical Fraternity, was held, March 11, at the Eutaw House, Dr. Wm. P. Martin being toastmaster.

**Forfeits Bail.**—Dr. William B. Hawkins, indicted on the charge of committing manslaughter by performing a criminal operation, failed to appear in the Criminal Court, March 15, and his bail of \$2500 was forfeited.

**Baltimore Deaths.**—For the week ended March 15 there were only 175 deaths, against 214 last year, being a general death rate of 14.44—for the whites only 13.90 per 1000. Among the causes were consumption 23, pneumonia 16, smallpox 2, scarlet fever 1.

**Post-Graduate Course.**—The College of Physicians and Surgeons, Baltimore, announces a series of post-graduate courses to be held from April 28 to June 9, designed for practitioners of medicine who desire to spend a short time in advanced clinical and laboratory study, and keep in touch with the progress of the day. The course provides for classes in medicine, surgery, and medical and surgical specialties, and laboratory courses in clinical medicine, pathology, bacteriology and pharmacology.

**Personal.**—The Board of Charities and Correction have appointed Dr. W. H. Smith resident physician at Bayview Asylum, and Dr. Irving J. Spear resident physician for the insane department, vice Drs. N. G. Kierle, Jr., and Lindsay Peters, who have completed their year of service.—Dr. George L. Staley, aged 79, was knocked down on the street by a wagon, March 15, and badly bruised.—Surgeon P. E. McDonald, U. S. N., has been detached from the U. S. Naval Academy and ordered to report for duty on the cruiser *Olympia*.—Dr. Harry C. Jones, of the Department of Chemistry, Johns Hopkins University, has just published "The Elements of Physical Chemistry," the first comprehensive text-book of physical chemistry in the English language.—The Health Commissioner has appointed seven additional vaccine physicians to assist temporarily in the work. They are Drs. J. N. Fenton, Page Edmonds, Albert J. Underhill, James L. Hooper, Alexander McKee, James E. Heard, and I. R. Page.

## MICHIGAN.

**Hospital Burned.**—The hospital of the Great Northern Protective Association, Cheboygan, has been destroyed by fire, the loss amounting to about \$3000.

**Medical Inspection of Schools.**—The Health Officer of Detroit has commenced the daily medical inspection of schools, with a staff of thirty physicians.

**Borgess Hospital, Kalamazoo.**—The enlarged Borgess Hospital at Kalamazoo will be opened by the Sisters of St. Joseph some time this month. The new \$50,000 addition is almost completed.

**New Medical Society.**—It is proposed to form an ophthalmological, otological and laryngological society composed of physicians of Michigan and adjacent parts. The project is endorsed by Drs. Emil Amberg, Eugene Smith, Preston M. Hickey and Ernest L. Shurley. A meeting was held recently at the Hotel Cadillac, Detroit, to consider the organization of such a society.

**Prevalence of Disease.**—For the month of February, compared with the preceding month, meningitis was more prevalent; and typhoid fever and diphtheria were less prevalent. For the month of February, compared with the average for February in the 10 years, 1892-1901, scarlet fever, measles and smallpox were more than usually prevalent; and consumption, erysipelas, remittent fever, and diphtheria less than usually prevalent.

**Mortality in Michigan.**—There were 2665 deaths returned to the Department of State for February, a decrease of 160 from the number returned for the preceding month. As February is a shorter month than January, the death rate, on the contrary, showed an increase from 13.5 to 14.0 per 1000 population. There were 422 deaths of infants under 1 year; 150 deaths of children aged 1 to 4 years, and 897 deaths of elderly persons over 65 years. Important causes of deaths were as follows: Pneumonia, 369; tuberculosis of lungs, 173; typhoid fever, 38; diphtheria, 38; scarlet fever, 20; measles, 16; whooping cough, 18; meningitis, 45; influenza, 78; cancer, 114; accidents and violence, 100.

## NEW JERSEY.

**Atlantic City Hospital Improvements.**—On March 5 the children's ward and maternity ward, recently added to the Atlantic City Hospital, were opened for the reception of patients.

**State Tuberculosis Sanatorium.**—The legislature has before it a bill providing for the creation of a state sanatorium for consumptives. The bill has the sanction of the Medical Society of New Jersey.

**The Mosquito Must Go.**—The New Jersey assembly, after a long debate, has passed the mosquito exterminating bill by a vote of 48 to 9. The bill appropriates \$10,000 to the state experiment station for the purpose of making a scientific investigation of the habits, origin, and breeding places of the mosquito and their relation to malarial and other diseases. The money is to be expended by the state entomologist.

**Personal.**—Dr. W. S. Patterson has resigned as junior resident physician at the Atlantic City Hospital, and has gone to Philadelphia, where he will be an interne at the Blockley Hospital.—Dr. Herbert L. Cooper, Vineland, has moved to Newfield.—Dr. Girard J. Van Schott, Passaic, has inherited an estate in Holland, valued at \$130,000.—Dr. Henry B. Diverty has been made physician to the Woodbury Board of Health.—Dr. Daniel Stroek, Camden, has recovered from the immediate effects of septicemia.

#### NEW YORK.

**Memorial Meeting for Dr. Townsend.**—The Genesee County Medical Association held an adjourned meeting at Batavia, March 10, which took the form of a memorial to its late president, Dr. Morris W. Townsend, Bergen.

**Canandaigua Hospital.**—Mrs. F. F. Thompson, whose proposed gift toward the establishment of a hospital in Canandaigua was noticed in *THE JOURNAL* two weeks ago, has purchased the McKechnie mansion in the heart of the village, with grounds of six acres, for \$22,500, as a site for the hospital.

**Dr. Moore's Memorial.**—The following bodies have adopted resolutions in tribute to the memory of Dr. Edward Mott Moore: The Rochester Academy of Science, the Executive Committee of the University of Rochester, the Rochester Practitioners' Society, the Rochester Athenæum and Mechanics' Institute, the Rochester Public Health Association, the Rochester Pathological Society, Buffalo Academy of Medicine, and the Faculty of the Medical Department of the University of Buffalo.

#### New York City.

**French Hospital Benefits.**—By the performance of "Le Cid" at the Metropolitan Opera House, March 4, for the benefit of the building fund of the new French Hospital, \$5000 was added to the fund.

**New Home for the Ophthalmic Institute.**—The New York Ophthalmic and Aural Institute, under the charge of Dr. Herman Knapp, is to move from its old quarters in East Twelfth Street to a new edifice on Central Park West and 64th Street.

**Minturn Hospital Annex.**—Mrs. Andrew Carnegie has expressed her willingness to give \$60,000 to build an annex to the Minturn Hospital, in New York, to be used for smallpox patients. The authorities of the institution will consider the plan. The building was intended for diphtheria and scarlet fever cases only.

**Contagious Diseases Hospital for the Bronx.**—The senate has passed the bill authorizing the establishment of a hospital in the Borough of the Bronx, which may be used not only for emergency cases but for the reception of smallpox patients. As no opposition to the bill has developed, it is confidently expected that the bill will pass the assembly.

**New Home for Incurable Consumptives.**—The House of Rest for Consumptives, after various vicissitudes during the past ten years, has at last purchased for \$75,325 a fine plot of 27 lots, situated at Inwood-on-the-Hudson, at an elevation of 160 feet above the river. A double mansion now on the place will be quickly altered at a cost of \$10,000 to meet the requirements of the institution, which is conveniently accessible by railroad from the heart of the city. The endowment fund now amounts to \$450,000.

**Hospital Accommodations for Consumptives.**—Commissioner of Charities Folks has asked the Board of Estimate and Apportionment for \$40,000 to alter and equip the four buildings on Blackwell's Island recently vacated by the Manhattan State Hospital for the Insane. A large part of this sum is to be expended in building glass structures so that the patients can receive an abundance of sun and fresh air. It is estimated that 500 patients can be maintained here at a cost to the city of only \$18,000 a year.

**Vital Force Discredited.**—A recent item called attention to the arrest of a "Doctor" Armstrong, whose peculiar methods of treating by "vital force" had led to his arrest on charges of immorality. The so-called "doctor" turns out to be a "Rev." and an "L.L.D.," and from the testimony it seems as though his vital force was easily turned aside by such impedimenta as clothing, for the ladies were treated with nothing on but a night-gown or were completely disrobed. The court very naturally sent this healer to jail for six months.

#### OHIO.

**Fire at Speers Hospital.**—A fire broke out at the Speers Hospital, Dayton, March 9, which occasioned considerable alarm, but was extinguished by prompt action of the fire department, with slight loss.

**Dr. Loving's Loving Cup.**—Professional friends of Dr. Starling Loving, Columbus, recently presented him with a loving cup, as a mark of the esteem in which he was held by them. Dr. Darlington J. Snyder acted as master of ceremonies and Dr. Florus F. Lawrence made the presentation speech.

**Nu Sigma Nu Fraternity.**—The twelfth annual convention of the Nu Sigma Nu Fraternity was held in Cincinnati, March 14 and 15. About two hundred physicians were in attendance, the guests of Theta chapter. Dr. James Tyson, Philadelphia, was elected honorary president for the ensuing year. The next convention will be held in New York City.

**Cincinnati Hospital Internship.**—The competitive examination for internes to the Cincinnati Hospital resulted as follows: Drs. Max Dryfoos, J. E. Stemler, Moses Salzer, L. C. Hayne, A. O. Zwick, Medical College of Ohio; C. W. Maass and D. W. Bedinger, Miami Medical College; J. H. Shroeder, Cincinnati College of Medicine and Surgery. Drs. S. G. Zinke and H. L. Bowles, both of the Ohio College, were appointed alternates.

**Personal.**—Dr. John C. Reeve, Jr., Dayton, has left for a trip around the world and will be absent several months.—Dr. Walter A. Griess, receiving physician to the Cincinnati Hospital for the past five years, has resigned, the resignation to take effect the first of April. Dr. Griess will spend several years in Europe before entering private practice.—Dr. Herschel A. Russ, Hillsboro, has been appointed major-surgeon in the Ohio National Guard and assigned to the First Infantry.—Dr. Orin L. Kramer, New Salem, has opened an office in Hebron.—Dr. M. H. Koehler, Newark, is about to locate in Jacksontown; Dr. William L. Jackson of that place having moved to Zanesville.

#### PENNSYLVANIA.

**A Divided Victory.**—The trial of a Meadville osteopath for practicing medicine without a license resulted disastrously for both sides. After twenty-four hours' deliberation, the jury was equally divided, but finally acquitted the defendant, dividing the costs of the suit between him and the Meadville Board of Health which made the complaint.

**Portrait of Founder Presented.**—D. T. Watson, Pittsburg, has presented the University of Pennsylvania with a copy of the portrait of John Morgan, by Angelica Kauffman. John Morgan was not only the founder of the Medical Department of the University, but a member of the first class to be graduated in the college and to receive the degree of Bachelor of Arts.

**A Correction.**—A correspondent notifies us that the News note in the last issue which stated that the Philadelphia County Medical Society had refused to endorse the administration of the Municipal Hospital is incorrect. At the meeting referred to objection was raised to the consideration of two resolutions, and as unanimous consent is required for action on business matters at scientific meetings, no vote was taken on the resolutions.

**Surgeons for the Guard.**—The following appointments to the medical department of the National Guard were announced, March 7: Dr. Alfred G. Wood, Philadelphia, to be surgeon, with the rank of major, assigned to Third Regiment; Dr. John C. Hirst, Philadelphia, to be assistant surgeon, with rank of first lieutenant, assigned to Third Regiment; Dr. John L. Brubaker, Altoona, to be assistant surgeon, with rank of first lieutenant, assigned to the Sheridan Troop, and Dr. Edwin A. Nicodemus, Bownmansdale, to be assistant surgeon, with rank of first lieutenant, assigned to Governor's Troop.

#### Philadelphia.

**Free Hospital for Poor Consumptives.**—At the recent annual meeting of the Free Hospital for Poor Consumptives, Dr.

L. F. Flick reported that out of 76 patients so far admitted to the sanatorium at White Haven 15 have been practically cured. Only favorable cases are sent to White Haven.

**Samaritan Hospital.**—Ground was recently broken for additions to the Samaritan Hospital. One building 50x50 feet, one story and basement in height, is for offices and reception room. Adjoining there is to be a three-story and basement structure, 42x85 feet, occupied by wards, baths, nurses' rooms and diet kitchen.

**Wills Eye Hospital,** under the care of the Board of Directors of City Trusts, is said in the annual report of the president of the board to be in immediate need of money. He states that the hospital equipment is antiquated, its buildings dingy, and the new buildings unfinished. The income from the Wills estate is not sufficient for running expenses.

**Visiting Nurses Society.**—At the recent 16th annual meeting all the old officers were re-elected; Mrs. Henry C. Lea is president, Miss Lucy Davis corresponding secretary. Two new branches have been opened within the past year, making four branches besides the central office. The Society is doing much to give the poor and those of moderate means skilful nursing.

**The Pediatric Society.**—At the last meeting of this Society Dr. John Lovett Morse, instructor in the diseases of children in the Harvard Medical College, delivered an address upon "Some Diseases of the Kidneys and Bladder in Infancy." A reception was afterwards given to Dr. Morse at the Aldine. On the same day, Dr. Morse delivered a lecture at Jefferson Medical College.

**The State Board of Health** has passed resolutions requiring cuspidors in railway trains, and an effort is being made to secure legislation providing a penalty for non-observance of the rule. The resolution provides that a cuspidor shall be placed at each end of the day coaches, and one furnished for each seat of the smoking cars; further, that thorough cleansing and disinfection of the vessels shall be done at the end of each run. It is thought by many that the habit of spitting should be done away with and not encouraged by conveniences.

#### RHODE ISLAND.

**Hospital Bequest.**—By the death of John A. Holt, Woonsocket Hospital receives the income from one-third of 100 shares of preferred stock of the United States Rubber Company.

**Compulsory Vaccination.**—Both houses of the assembly have passed an act providing for vaccination of children and revaccination of adults, and prescribing penalties for violation of this law.

**New Wing to Newport Hospital.**—Mrs. Cornelius Vanderbilt has accepted plans for a new wing to Newport Hospital which she will have erected in memory of her late husband. The building will cost about \$250,000.

**State Sanatorium for Consumptives.**—There has been introduced in the general assembly a bill authorizing the appointment of a board of five persons to have control of a state sanatorium for consumptives, and appropriating \$100,000 to inaugurate the project.

#### GENERAL.

##### Smallpox.

**United States:** According to the health reports at Washington the number of cases throughout the country amounted last week to over 22,000.

**Arkansas:** Dr. George M. D. Cantrell, president of the State Board of Health, gave out the following statement: We do not know how many counties in the state have smallpox and we have no means of knowing except as reports may be made to the Board from time to time and requests made for the appointment of county boards. These requests are complied with in a perfunctory manner and there our power ends. We have no funds to work with, not even to pay for postage stamps, so what can we do? A year ago I went to Magazine to inspect the smallpox situation and lost considerable time. I have not yet received a cent for even the expenses of the trip, and some time ago I told Governor Davis I would make no more trips and pay my own expenses.

**California:** The health officer of Sacramento County reports 25 cases of smallpox in the county, all light and all quarantined.

**Connecticut:** The State Board of Health announces that during 1901, 78 cases of smallpox were reported in the state. These were distributed through 15 towns. During the year 1902 up to the present date, there have been reported 47 cases, making a total of 125 cases during the last 14½ months. Of the 125 cases thus far only 8 have proved fatal, being a death

rate of between 6 and 7 per cent. only. The cases of the present year have occurred in 14 different towns. The 125 cases have been distributed among 24 different towns in the state. The remaining 144 towns are equally liable to the disease. Every new invasion of this disease is an occasion of much fright and anxiety, and always of very extraordinary expense. The method of preventing an invasion of smallpox is so simple that it is truly astonishing that an intelligent community neglects it. It is simply doing before the disease appears exactly what they all do immediately after its appearance. That is—vaccinate. Vaccinating is one hundred times cheaper than quarantining. An epidemic of smallpox has never occurred in a well vaccinated community. Vaccination should be performed in infancy, a re-vaccination at the age of 12 or 14 and subsequent vaccinations whenever an individual is exposed, or as in the present instance when an epidemic is prevailing.

**District of Columbia:** Referring to the matter of efficacy of vaccination in lessening the number of cases of smallpox in a community, the health officers state in reference to the 19 cases of smallpox reported since January 1, that 17 of the patients had never been vaccinated, one was never successfully vaccinated and one was successfully vaccinated nineteen years previous to the present attack of the disease.

**Illinois:** The Chicago Department of Health reports that among the six new cases of smallpox discovered during the week—none ever vaccinated—one was a cook in a large hotel. He worked in the kitchen for eight days while broken out with the disease. While there has been an increase of 162 per cent. in the total number of smallpox cases reported for the whole country since February 8, over the number reported during the corresponding period last year, there has been a reduction of a little more than 40 per cent. in the Chicago territory in which the active campaign by the railroad companies and health authorities is being carried on.

**Indiana:** There were 758 cases of smallpox reported in 36 counties and 3 deaths. In the corresponding month last year there were 165 cases in 15 counties and 2 deaths. The increase in deaths from smallpox was 50 per cent. and the increase in cases 176 per cent. The area of infection increased 140 per cent. The smallpox deaths occurred one each in Cass, Pulaski and Shelby counties.

**Kansas:** Dr. W. B. Swan, secretary of the State Board of Health, on March 12, issued his report for February on smallpox. During the month he was notified of 421 cases of the disease in the state, but no deaths resulted. In February, 1901, there were 1335 cases and 10 deaths.

**Louisiana:** In New Orleans during February there were 9 cases of smallpox, with no deaths.

**Maryland:** At the monthly meeting of the State Board of Health, March 12, it was stated that there were but 4 cases of smallpox in Maryland outside of Baltimore, and that they are widely separated. Four smallpox convalescents were discharged from quarantine March 15; 5 patients are left, 3 being convalescents.

**Michigan:** Reports to the State Board of Health show that smallpox was reported at 140 places last week. No death occurred from the disease during the month.

**Nebraska:** An Associated Press telegram states that: "Following a meeting of the State Board of Health at which it was announced that there were 764 smallpox cases in the state, the secretary of the board was ordered to communicate with the federal authorities as to the best means of stamping out the disease. It was decided to telegraph the Army and Navy Hospital Marine Corps to send a special messenger to Nebraska and the message will go to Washington some time during the day."

**New York City:** For the past few weeks there have been between 50 and 60 new cases of smallpox, which is higher than for the same period last year. Thus, in January of the present year there were 83 cases as against 59 for the same month of 1901, and 120 in February, 1902, as against 95 for that month in 1901. There have been over 400 cases of smallpox in this city since last August, and at present there are 160 cases in the hospital, a larger number than at any other time this year. On the other hand, the health department have been vaccinating about 34,000 persons a week during the past four weeks, 200 vaccinators being at work.

**North Dakota:** Dr. Henry H. Healy, Michigan, president of the State Board of Health, states that 186 cases of smallpox have been reported in North Dakota during the two weeks ending March 8.

**Washington:** Dr. Walter F. Morrison, Spokane, physician of Spokane County, reports 76 cases of smallpox during February.

**Public Health Bills in Congress.**—An extensive correspondence has been going on for some time between the Committee of the American Medical Association on National Legislation, consisting of Drs. H. L. E. Johnson, Washington, D. C.; William H. Welch, Baltimore, and William L. Rodman, of Philadelphia, with Dr. Edmond Souchon, president of the State Board of Health of Louisiana and the other state health officers throughout the country, and a number of other prominent members of the American Medical Association in relation to the Spooner Health Bill, the Perkins and Hepburn Marine Hospital Bill, the Ray Health Bills now pending in the National Congress. The correspondence culminated in the calling of a conference of state health officers by Dr. Edmond Souchon, which met at Washington City on the 12th and 13th inst. Among those present were Dr. Edmond Souchon, president of the Louisiana Board; Dr. James Evans, secretary of the South Carolina Board; Dr. A. H. Doty, quarantine officer, New York port; Dr. U. O. B. Wingate, secretary board of Wisconsin; Dr. William H. Welch, president, Maryland State Board; Dr. H. M. Bracken, secretary Minnesota Board; Dr. Henry D. Holton, secretary Vermont Board; Dr. Nowber, secretary Delaware Board; Dr. Green of Charleston; Dr. Cooper of Delaware; Dr. J. F. Durgin, quarantine officer, Boston port; Dr. McAllister of Missouri; Dr. T. G. Simmons, president South Carolina Board; Dr. Lewis, New York Board; Dr. Heller, Pennsylvania Board; Dr. W. H. Sanders, state health officer of Alabama; Dr. W. D. Goodman of Mobile; Surgeon-General Wyman, Marine-Hospital Service, and Dr. H. L. E. Johnson, Washington, D. C., representing the American Medical Association. The above-mentioned bills and their provisions were thoroughly discussed, and the conference decided by a favorable vote of all present except one, to recommend the passage of the Hepburn Bill, with a slight modification to Section 7. The following was adopted, and a committee of three members consisting of Dr. H. M. Bracken of Minnesota, Dr. Edmond Souchon of Louisiana, and Dr. Wm. H. Welch of Maryland, were appointed, together with Surgeon-General Wyman and Dr. H. L. E. Johnson, to appear before the Committee of the House and Senate and urge the adoption of the bill recommended as modified. The Committee appeared before the Committee of the House on Interstate and Foreign Commerce on the 13th inst., individually addressed the Committee on the subject and presented the matter agreed upon by the Conference as follows:

WASHINGTON, D. C., March 13, 1902.

Hon. W. P. Hepburn, Chairman of the Committee on Interstate and Foreign Commerce, House of Representatives.

Sir:—The President and Executive Officers of State Boards of Health and Port Quarantine Officers called to conference by Dr. Edmond Souchon, of New Orleans, met at the Metropolitan Hotel, Wednesday, March 12, to discuss the bills now before Congress bearing upon the creation of a National Health Service, namely, the Ray Bill (H. R. 10,535) and the Hepburn Bill (H. R. 7189).

Twenty medical men were present, representing all sections of the country. By request, Surgeon-General Wyman, of the Marine-Hospital Service, and Dr. H. L. E. Johnson, Chairman of the Legislative Committee of the American Medical Association, were also present.

After thorough discussion of the bills, a committee of five was appointed to consider the points discussed and report to the afternoon session of the conference. This committee made its report at 5 p. m., recommending but slight change in the Hepburn Bill (H. R. 7189). The only change that was suggested in this bill was based upon the wish of the physicians in conference to have the privilege of asking for a conference with the National Health Authorities at Washington, when in their judgment such conference would seem desirable. The changes are embodied in section 7 of said bill, a copy of which section, as amended, is herewith submitted.

Sec. 7. "That when in the opinion of the Surgeon-General of the United States Health Service the interests of the public health would be promoted by a conference with the State or Territorial boards of health authorities, the District of Columbia included, or on the application of five state boards of health or quarantine officers, the Surgeon-General of the United States Health Service is authorized to invite representatives of state boards of health and quarantine officers to send delegates, not more than one from each state or territory and District of Columbia, to said conference, and when thus convened said delegates shall be entitled to reimbursement for their necessary expenses of travel and of maintenance not exceeding five days at the place of conference in accordance with such regulations as may be made by the Secretary of the Treasury."

With these changes the Hepburn Bill (H. R. 7189) was indorsed by the conference, and a committee of three was appointed to present these facts to your honorable committee, it being considered unnecessary to take up the time of your Committee with the hearing of a larger number of men.

We are indebted much to Surgeon-General Wyman for advice and consultation in bringing about this harmonious feeling, and we submit our report with the hope that the Hepburn Bill may soon become a law. The necessity of a National Health Body has long been recognized, and it has been sorely needed. Such bodies already exist in the countries bordering upon the United States, namely, Canada to the North, and Mexico to the South.

Respectfully submitted, H. M. Bracken, Minnesota; Edmond Souchon, Louisiana; William H. Welch, Maryland.

On motion these resolutions were transmitted to the Chairman of the Committee on National Legislation with the request that they be approved by that Committee and the annual conference with the State Societies which meets in June, and that they urge before Congress the passage of the bill as amended.

The same Committee had a conference with Senator John G. Spooner, a member of the Committee on Public Health and National Quarantine of the Senate, and discussed the amendments proposed by the Conference, and urged its passage as amended. After a full discussion, Senator Spooner suggested the following verbal changes in the substitute for Section 7 of the Perkins Bill as modified by the Conference as follows:

"Sec. 7. That when in the opinion of the Surgeon-General of the United States Health Service the interests of the Public Health would be promoted by a conference with the State or Territorial Boards of Health or health authorities, the District of Columbia included, he may, or on the application of five state boards of health or quarantine officers, the Surgeon-General of the United States Health Service shall invite representatives of state boards of health and quarantine officers to send delegates, not more than one from each state or territory and District of Columbia, to said conference."

The Committee, including the Surgeon-General of the Marine-Hospital Service, Dr. Wyman, and the Chairman of the Committee on National Legislation of the American Medical Association, Dr. H. L. E. Johnson, approved of the recommendation of Senator Spooner and presented the following to be used by him in connection with their original recommendation when the matter is taken up for consideration by the House and Senate Committees:

WASHINGTON, D. C., March 13, 1902.

Hon. John G. Spooner, United States Senate.

Sir:—We, the representatives in the Committee of the Conference of State Health Officers, approve of the suggestions offered by you and set forth in the enclosed modified Section 7 of Senate Bill 2162, known as the Perkins Bill, and in so doing feel that we are expressing the views of the conference.

Respectfully, H. M. Bracken, Minnesota; Edmond Souchon, Louisiana; William H. Welch, Maryland.

#### CANADA.

**Sir William MacDonald, Montreal,** has donated \$10,000 for the purpose of erecting a new day nursery building in that city.

**Vaccination and Smallpox in Montreal.**—Dr. Laberge, the medical health officer of Montreal, has reported to the health committee of that city that since last November 335 cases of smallpox had been reported in the city, the average varying from two to four cases per day. The report also showed that from January 15 to February 28, 24,233 people had been vaccinated.

**Smallpox and Vaccination at Toronto University.**—The student body of Toronto University has been considerably exercised during the past week owing to the fact that smallpox had gained a hold on a fourth-year science man. President London, on hearing of the facts, immediately communicated with the city medical health officer, Dr. Charles Sheard, and also with the Provincial Secretary of the Board of Health. The case was at once removed to the Isolation Hospital and then a general vaccination of the entire student body of the several departments of the University was undertaken.

**New Civic Hospital for Montreal.**—At last Montreal is to have a new Contagious Diseases Hospital. The proposal passed through the City Council almost unanimously last week. It is to be built on Fletcher's Field, will be for the care of patients suffering from infectious diseases other than smallpox, and will cost \$50,000. The old smallpox hospital will remain for that class of patients. Although the Catholic body, headed by Archbishop Bruchesi, made strong representations to Council for a separate institution, the Council voted that only one hospital was desirable. The Archbishop states he will not accept a non-sectarian hospital for his people.

**Ontario Medical Council Affairs.**—The special committee of the Ontario Legislature appointed to consider the amendment to the Ontario medical act with regard to eliminating from the Ontario Medical Council the Homeopathic and College representation has been received and adopted by the House. According to this report it is proposed to submit, probably early in the fall, questions to the medical practitioners of Ontario which would afford definite information upon points which have long been in dispute, namely, the constitution and representation in the Council. If there should appear much desire for a change, the Government will then act in the matter. In the meantime the report proposes that the physicians who have refused to pay their annual assessments to the Council shall have votes as well as those who have paid them.

**The Victorian Order of Nurses.**—During the past week the Board of Governors of the Victorian Order of Nurses held their annual meeting at Ottawa. The principal feature in connection with the work of the order during the past year was the success which attended the efforts put forth in connection with the Lady Minto Cottage Hospital Fund, the sum of \$25,000 having been raised almost entirely by the efforts of Lady Minto alone. From this sum \$6000 has been paid out on hospitals in the Canadian Northwest Territories, and \$8000 more has been allotted for similar purposes. New branches of the order were opened at Picton, N. S., and Dauphin, Man.; at the former place a wing of the Marine Hospital is now supplied with nursing service by the Victorian Order. The financial report stated that there had been some falling off in the endowment fund to yield \$2500 annually.

**Tuberculosis in Quebec Province.**—The Government of the Province of Quebec has been requested by a member of the local legislature to produce all papers and correspondence received during the past year regarding tuberculosis and its treatment. This will be provocative of serious discussion in the House, and an endeavor will be made to obtain from the Government assistance for the establishment of sanatoria for the treatment of consumptives. The Province of Quebec already possesses a sanatorium, but it does not derive any financial assistance from the Province. This is the Laurentian Sanatorium situated at St. Agathe des Monts, not far from Montreal, which is directed by Dr. Arthur J. Richer. Dr. Paul E. Prevost, recorder of vital statistics for the Province, has prepared a report which shows that in 1897 3079 persons died in that Province from Tuberculosis; in 1898, 2876; in 1899, 3085; in 1900, 3015. The figures show that the death-rate from tuberculosis is three times that of any other disease, except infantile diarrhea. In Montreal alone in 1900 there were 791 deaths from consumption.

**Dominion Registration.**—Dr. Thomas G. Roddick, M.P., received the applause of both sides of the House of Commons on the conclusion of his address before that body on the occasion of the second reading of his bill to provide for a Dominion Medical Council. Objection was raised by one of the members from the Province of Quebec as to the constitutionality of the measure, some one also stating that the Medical Faculty of Laval University was quietly antagonistic to the measure. The medical profession throughout Canada, however, are practically a unit in the matter, but they are fearful that the premier, Sir Wilfred Laurier, may place his veto on the bill on account of this mooted constitutionality. Owing to the fact that Dr. Roddick wished his bill to be referred to a special committee of the House, Sir Wilfred did not oppose its second reading. The constitution of the proposed Dominion Council, as now set down by its promoter, will number 39 members, as follows: Eight from the Province of Quebec, Laval University being given an additional member; 9 from Ontario; Nova Scotia and Manitoba 4 each; New Brunswick, British Columbia and the Northwest Territories, 3 each; Prince Edward Island, 2; the Homeopathic body, 3. The medical population in the Northwest Territories has grown in the past year from 110 to 211.

## Correspondence.

### The Journal Abstracts.

DAYTON, OHIO, March 4, 1902.

*To the Editor:*—Aunt your editorial on "abstracts" in issue of March 1, p. 587, permit me to say that to this member of the profession they are an *extremely* valuable addition. While the papers of the Association and the original communications may or may not strike my fancy, the abstracts always contain something of interest to me. Do not give up the abstracts.

Respectfully, WILFRED TAYLOR, M.D.

### Medical Lectures to the Laity.

MACON, GA., March 16, 1902.

*To the Editor:*—I am impressed with what you have had to say in THE JOURNAL, March 1, page 556, about the propriety of medical societies having an authorized medical instructor of the people. I think the profession needs to enlighten the public and they would be glad to hear the truth from such a source.

Yours very truly,

M. M. STAPLER, M.D.

### Creosote in Pneumonia.

FT. WORTH, TEX., March 15, 1902.

*To the Editor:*—In order to prepare a statistical table showing the results of the treatment of pneumonia with creosote or creosote carbonate, I ask the aid of the profession. I request every physician who has given the treatment a trial to kindly send me, on a postal card, during April, 1902, the number of cases treated and number of deaths; state whether of record or an approximation.

Please answer yes or no to the following questions: 1. Do you believe creosote ever aborts pneumonia? 2. Do you believe the majority of cases are mitigated by it? 3. Have you found cases which, having plenty of time, were entirely uninfluenced by it?

To every one favoring me with a report, I will mail a copy of the condensed reports.

I. L. VAN ZANDT, M.D.

### Book Review Criticised.

PHILADELPHIA, PA., March 1, 1902.

*To the Editor:*—The review of my book, "Studies of the Internal Anatomy of the Face," in your issue of January 18, reminds me of the story of a boy who was being paddled by his father for some supposed dereliction. In spite of the fact that the punishment was vigorously applied, the boy kept laughing. The old man, astonished and angry that the thrashing failed to produce its usual effect, yelled out: "What are you laughing about, you young jackanapes?" "I'm laughing at you, Dad; you're dead wrong this time. You're licking the wrong boy. I didn't do it!"

Two statements are attributed to me in this review for which no foundation can be found in the book. The first of these is in the second paragraph, which says: "The illustrations are reminders to the student of anatomy that as the author remarks 'owing to the degeneracy of the face and jaws it is possible, though doubtful, that in a thousand bones two or three should be found which exactly correspond with the typical bones so pictured.'" Observe that the so-called quotation is introduced by the phrase, "as the author remarks." The author made no such remarks. Here is what he did say: "There is, doubtless, a typical or typical form for each bone, but it is not often found in nature. If we were to photograph a thousand temporal bones for example, and make a composite of the entire number, the composite would properly be accepted as figuring the typical temporal. It is possible, though doubtful, that in a thousand bones two or three could be found which exactly corresponded with the typical bone so pictured."

There is not a word about "degeneracy;" no attempt is made to ascribe a cause for the condition referred to. There was no thought of "degeneracy" in connection with the matter, nor is there anywhere in the context any justification for lugging it in. The misquotation in your review seems to me to be a wilful perversion of facts, for what purpose I can not conceive.

The second misrepresentation of what I said is in the last sentence but one of the article: "His views as to the predominance of the cerebellum as a cause of prognathism would appear antiquated to modern anatomists." I said nothing of this kind. What I did say was that a large cerebellum and the prehensile dentition of the savage were found together, but I had no thought of suggesting the one as the cause of the other.

Legitimate criticism of the book was invited when it was sent for review. It was the right and duty of the reviewer to point out its faults. But I submit that the perversion of plain statements, the setting up of a man of straw—for the building of whom no material is to be found in the book—for the fleeting happiness of demolishing him, is not legitimate criticism. I can only account for it on the supposition that your reviewer has the "degeneracy" fad in virulent form.

Yours truly,

M. H. CRYER, M.D.

### The Will of the People, Not of an Oligarchy.

BOSTON, MASS., March 13, 1902.

*To the Editor:*—Prof. William T. Sedgwick, Boston, in an address published in a recent number of THE JOURNAL "confesses with sorrow" the lack of success of efforts to prevent the study of "temperance physiology" as now required in the public schools of this country.

He first offers in defense of his opposition the fact that Horace Mann, in 1842, did not include temperance physiology in his essay on "The study of Physiology in the Schools," but he omits to add the significant accompanying fact of history, namely, that the recommendations of Horace Mann's essay that "physiology should be taught in the schools," aroused in Massachusetts such a storm of bitter opposition from the doctors and men of official science, that the existence of the Massachusetts State Board of Education and its secretary, Horace Mann, were saved by only a hair's breadth from being entirely legislated out of office. But time has vindicated Horace Mann's recommendations while his opponents are forgotten.

Sixty years have passed, and Massachusetts, as well as every state, and the National Congress have made physiology and hygiene, which latter includes the nature and effects of alcoholic drinks and other narcotics, a mandatory public school study. Prof. Sedgwick is now objecting, not to this study, he says, but to the legal specifications which have made it a success. First, he objects to its being taught "to all pupils." He does not tell when or by what class of pupils he would have it omitted. In our country "all pupils" of to-day are destined to be the sovereign people of to-morrow. Hence, looked at from the standpoint of the state, it can not afford that one single pupil should not receive the utmost instruction on this subject needed to fit that pupil for a future sovereignty of intelligent sobriety.

From the standpoint of the individual, we ask, from whose child shall this educational method for the prevention of intemperance be withheld? Shall it be from the children of the poor, the rich, the foreign born, or the home born? We are answered by the command of the greatest of all Teachers that the supreme message for the prevention of evil and the establishment of right should be given "to every creature" in "all the world." That inclusive command and precedent not only justifies all pupils getting this education, but implies neglect of duty if it is excluded from any.

If Prof. Sedgwick's objection is to the requirement of the study through specified grades as his reference to the Illinois law implies, we answer: The formation of right habits is the object sought. The child's habits are rapidly formed, new ones each year as it proceeds through the first primary to the high school. It is therefore self-evident progressive instruction which will guide in the formation of right habits should be given especially during the primary, grammar and first year of the high school in order to keep pace with and guide the child's development. The boy, or girl, who leaves school at any point in the school course with as much knowledge as he can comprehend of the laws of health, including those which warn against the use of alcoholic drinks and other narcotics, has thereby a most valuable equipment for the battle of life.

The diffusion of this knowledge in our country is now as universal as the schools. It does not, we grant, add to the value of brewing stocks, but evidence is not lacking that it is proving of great value to the human stock in the increase of health due to better knowledge of sanitary laws, consequent lengthening of life, increased sobriety of the American workman, which sobriety is acknowledged to be one cause of the commercial supremacy of this country in the markets of the world, etc.

Prof. Sedgwick says he was "shocked," "much disturbed to find that an author had actually felt bound to weave in a lesson on alcohol with his discussion of the physiology of muscle, of nerve, of digestion, of vision, and each of several other sections of the subject."

Why should not the deleterious effects of alcohol on muscles be taught in connection with the study of the physiology and hygiene of the muscles? Prof. E. Destrée, University of Brussels, by actual experimentation proved that the "total work product obtained (from the muscles) with the use of alcohol is less than that obtained without it." Our boys and girls need to know that fact. Why should not the fallacy of the idea that alcohol is an aid to digestion be pointed out in connection with the hygiene of digestion, when Prof. Chittenden distinctly says of his experiments: "The results obtained suggest a tendency toward prolongation of the period

during which the meat remains in the stomach when alcohol fluids are present." Why is not the treatment of the physiology and hygiene of the nerves the proper place for pointing out the effect of alcohol upon them when H. J. Berkeley, M.D., of Johns Hopkins University, reported as a result of the experiments he performed for the Committee of Fifty that alcohol "possesses the quality of destroying the protoplasm of the nerve cells and annulling its functions." Why not in teaching the care of the eyes mention the danger from the use of alcohol when the senior surgeon of the New York Ophthalmic Hospital says: "The respectable moderate drinker who never takes too much or oversteps the boundary line of decency but goes round half full all the time exposes himself to the risk of losing his eyesight, which in this case is incurable."

To Prof. Sedgwick's complaint that some laws require text-books on this subject for pupils' use and specify the amount of temperance matter they shall contain, etc., we reply: The tendency of careless, unsympathetic school boards to fail in providing well graded text-books on this subject, books that contain the matter the law requires taught as one source of information for pupils sufficiently advanced to use text-books on other subjects, induced the National Congress and many states to legally require that such text-books shall be provided. This requirement has led to the preparation of a valuable school literature by men of acknowledged scientific standing and to the revision of nearly all the imperfect books. Why should Prof. Sedgwick complain? No one has proved these books inaccurate, nor that their use in the schools has not contributed to individual and public good. The old unrevised, ungraded, and therefore unindorsed books contain such teaching as the following, for children in primary grades: "the tendon of Achilles is the tendon of the gastrocnemius and solens muscle," a statement as clear as mud to the primary child. The people want better books for their children and hence have so legislated that better books are produced.

Prof. Sedgwick further charges me with being a follower of the teachings of Sir Benjamin Ward Richardson (whom he calls an "able but erratic physician"), and with being "the creator of this astonishing movement" for temperance education. I happened to have had enough previous study in chemistry to enable me to appreciate the reports of his experimental work on alcohol and no one has proved his findings inaccurate. Although I never saw Dr. Richardson, he taught me much which I have tried to pass on.

As to being the "creator" of this movement, while I do not deny nor apologize for having tried to serve my country through helping to get this education for its children, I hasten to say that without the aid of the hundreds of thousands of consecrated women in the Woman's Christian Temperance Union, the organized motherhood of this and other lands, whom it is my fortune to represent in this matter, without the coöperation of the good men in this and other countries, in the National Congress, state legislatures and parliaments, every state in the United States would not now have a temperance education law nor would the movement have become, as Prof. Sedgwick admits, world-wide.

Prof. Sedgwick, in referring to Commissioner Harris' connection with the Advisory Board of this Department, says: "As to the propriety of the Commissioner's connection with this movement I make no comment." The Advisory Board of this department consists of eleven members, six of them physicians, three of whom are professors in medical colleges, three men eminent in education and two in ethics. The committee from this Advisory Board whose duty it is to examine and pass on text-books consists of five of the physicians mentioned above, one of the educators, two representatives of ethics, and the Superintendent of Scientific Temperance Instruction of the World's and National Woman's Christian Temperance Union. Dr. Harris, the National Commissioner of Education, and Dr. Barrows, President of Oberlin College, members of the Advisory Board, are not on its text-book committee. Hence, there is no occasion for Prof. Sedgwick's subtle reference to Dr. Harris' position on this Board. The American people will feel it just and right that their national commissioner of edu-

cation should be an adviser of a department of education which has been legally adopted by the whole people.

If Prof. Sedgwick had only quoted the whole preamble and recommendations passed by the National Superintendents of Schools in Chicago last year, the readers of THE JOURNAL would have seen that their action was positively on the side of temperance instruction and not mere "guarded paragraphs" as he claimed. They repudiate Prof. Atwater's teachings of the year before as to alcohol being a food, and put themselves squarely on record on the whole subject as the following paragraphs from their report not quoted by Prof. Sedgwick shows:

The department of superintendence agrees cordially with the special advocates of the temperance cause in holding that everything which public instruction can do in the battle against intemperance ought to be done, and that both physiology and hygiene should be so taught as to leave in the minds of children and youths as adequate and proper knowledge of the effects of alcoholic drinks, stimulants, and narcotics on the human system.

Since the last meeting of this department there has been considerable discussion of the question as to whether alcohol under any conditions is properly to be defined as an article of food. Medical authorities are quoted in support of both sides of this question, but no authority has been found to maintain that alcohol is a food in the ordinary sense of that term. The question of the supposed food value of alcohol is a technical one for medical experts to determine, and not one which needs to concern the man and woman who are engaged in the work of public instruction of children and youth. For them it is enough to know that its use as a beverage is injurious, and that all authorities agree in deprecating the formation of the drinking habit and in commending all practicable efforts through public instruction to promote the cause of temperance.

Prof. Sedgwick appears to have some fears that a writer who desires to publish an elementary text-book on physiology and hygiene, before he can obtain a publisher or a market, may have to secure the indorsement of Mrs. Mary H. Hunt, etc. Anybody can write a text-book on this subject as far as the Scientific Department of the Woman's Christian Temperance Union is concerned, but the mothers in any community have a perfect right to oppose their children studying that book, if, in their judgment, it fails to teach the whole truth against the most destructive of human habits. They have a right through organization to secure and protect this form of education for their children, and to appoint one of their number to act with them in searching for truth, and, aided by men of science, to refuse indorsement to books that do not contain the truth. I make no apology for its being my fortune to have been thus officially appointed, and woe is me if in this I fail in aught of my utmost duty, for history will show that organized motherhood in securing and protecting this education for all the children of this nation, has prevented the greatest peril to our government of the people, namely, the lack of capacity for self-government resulting from the use of alcoholic drinks and other narcotics.

As to the publisher's part in this connection, I would say: The publisher is a business man who knows that his success depends upon his supplies meeting the demands of the market. If the condition prevails which Prof. Sedgwick describes, it is good evidence that publishers have found that the American people do not want their children to study what the publishers themselves call "rum books" and that the indorsement of this department is a guarantee to the public that the books bearing that indorsement are not of that character but instead contain the truths the people want taught their children. Therefore, the writer who wishes to put a "rum book" on the market must find publishers who will ignore the law of supply and demand; or, he must persuade the people to allow their children to be sacrificed to the Moloch of intemperance either for his personal gain or to avoid shocking the sensibilities of scientific gentlemen who see no place in physiology and hygiene for warning against that disobedience of hygienic law which causes, as Gladstone said, more havoc to the human race than war, pestilence and famine.

No man has ever yet been able to present a reasonable argument for opposing the temperance education movement. The brewers and distillers, of course, can not imagine any other than a financial motive that could induce the devotion and labor that has brought this movement to its present position in this country and the world. Hence they charge, and have from the first, that it is a "book job." In the absence of reasonable objection other opponents reiterate this liquor dealers' charge. Prof. Sedgwick falls into line with them when he attempts to support his objection with a quotation from a

letter written, he says, by a representative of a publishing house which charges that "financial benefit" is the motive of the temperance physiology movement. On reading that, I at once wrote Prof. Sedgwick asking for the name of his informant and whether that informant had submitted any evidence in support of his statement. Prof. Sedgwick replied that he did not feel at liberty to give the name of his informant who, he says, "did not submit any evidence bearing upon his opinion." In other words, Prof. Sedgwick makes this accusation public without examining the evidence for the same and without knowing so far as he reports whether any such evidence existed. If the man who made this charge is reliable, why should he be unwilling that Prof. Sedgwick should mention his name? As to the intimation of a mercenary motive, I state that neither I, nor my Advisory Board, nor the constituency we represent, are one penny richer for the sale of any text-book on this subject bearing our indorsement. Resort to such charges is evidence of conscious poverty of argument against this movement. As to the promoters of temperance education in the public schools being a "self-constituted oligarchy," as Prof. Sedgwick says, we reply:

The Superintendent and Advisory Board of the Department of Scientific Temperance Instruction in Schools and Colleges are elected by the World's and National Woman's Christian Temperance Union to take charge of the work of that society for the study of temperance physiology in schools. Thus this department has for its constituency the largest organization of women in the world, who are banded together to secure as one of their objects, the protection of this special education for their children. Hence, to call the work of this department that of a "self-constituted oligarchy," as Prof. Sedgwick does, shows utter misapprehension of facts. "A self-constituted oligarchy," i. e., "power exercised by a few" who are self-appointed, could not write its ideas embodied in law on the Federal statute books and those of all the states of this great republic. The laws requiring this study and whatever is necessary to its being taught represent the 75,000,000 American people who have decided that their children shall have this special education. It is simply futile to try to belittle this movement by efforts to make it appear as anything less than a national one which is rapidly becoming world-wide.

MARY H. HUNT,

World and National Superintendent of the Department of Scientific Temperance Instruction of the Woman's Christian Temperance Union.

## Married.

JOHN R. GROH, M.D., Lebanon, Pa., to Miss Annie Behney, of Fredericksburg, Pa.

JOHN B. UNDERWOOD, M.D., St. James, Mo., to Miss Nora B. Bibb, of Elsberry, Mo., March 5.

THOMAS A. KILLIP, M.D., Rochester, N. Y., to Miss Louisa Barnes, of Dunkirk, N. Y., March 6.

DAVID F. WEEKS, M.D., Trenton, N. J., to Miss Maude A. Clampitt, of Oak Lane, Philadelphia, March 12.

## Deaths and Obituaries.

Arthur Titus, M.D., Cincinnati College of Medicine and Surgery, 1865, a prominent member of the profession in Portsmouth, Ohio, died recently. The Hempstead Academy passed the following resolutions of respect and sorrow, at its meeting, March 10:

WHEREAS, This Society learns with sincere sorrow of the death of our fellow laborer, Dr. Arthur Titus, we desire to express our testimony and sympathy in this occasion: therefore, be it

Resolved, That Dr. Arthur Titus was the highest type of the general practitioner, with a cheerful disposition, a strong decided character and a scientific mind, which was best displayed at the bedside of the sick. Ethical in all his intercourse with his fellow practitioners; present whenever possible at our society meetings and ever willing to extend his aid and counsel to his associates in medicine and surgery, a patriot that devoted three years of his life as surgeon during the Civil war.

Resolved, That we extend to the bereaved wife and family our great sympathy; and that we will so far as possible attend his funeral in a body, and that a copy of these resolutions be given to his family. [Signed] M. S. Pixley, M.D., P. J. Kline, M.D., S. S. Halderman, M.D., Committee.

**Lawrence Ashton, M.D.** New York University, 1885, one of the leading physicians of Northern Texas, and a member of the American Medical Association, died at his home in Dallas, March 6, after a brief illness, aged 57. He was a private student of the late Prof. A. L. Loomis of New York. During his residence in Texas he was an active worker in the State Medical Association; he was a member of the legislative committee two years ago, and was an earnest advocate of the present law governing the practice of medicine. He was at the time of his death president of the faculty of the Dallas Medical College, medical department of Trinity University and professor of practice of medicine.

**Thomas A. Keables, M.D.** University of Georgetown, Washington, D. C., 1872, formerly of Wilmington, Del., but of late years a member of the medical staff of the veterans' Home, Napa, Cal., died at that place, March 4, from chronic Bright's disease after a long illness, aged 58. He served throughout the Civil war, and represented Mono, Alpine and Inyo counties in the thirty-second session of the California legislature.

**Arthur T. Muzzy, M.D.** College of Physicians and Surgeons, New York, 1879, a specialist on the eye and ear, assistant surgeon at the New York Eye and Ear Infirmary, a member of the Board of Managers of Christ Hospital in Jersey City, and consulting physician for the eye and ear at Isabella Heimath Home for Aged Couples, died from heart disease at the Presbyterian Hospital, New York City, March 4, aged 50.

**A. Philo Drake, M.D.** Western Reserve University, Cleveland, 1850, a veteran of the Civil war, one of the best-known physicians of Barry County, Michigan, where he had practiced for more than half a century, and a member of the American Medical Association, died at his home in Hastings, very suddenly, March 10, aged 74.

**Andrew J. Bowers, M.D.** Miami Medical College, Cincinnati, 1854, president of the Dearborn County Medical Society, a member of the State Medical Society, for two terms a member of the legislature, and for nearly half a century a practitioner at Moores Hill, Ind., died at his home, March 6, from pneumonia, aged 76.

**Andrew B. Chapin, M.D.** University of Michigan, Ann Arbor, 1861, a practitioner of Mt. Clemens, and for two years mayor of that city; a surgeon throughout the Civil war, and at one time a member of the faculty of the Detroit College of Medicine, died at his home, March 9, from paralysis, aged 64.

**James W. Hines, M.D.** University of Virginia, Charlottesville, 1861, during the Civil war a surgeon in the Confederate service, but for the last 22 years a practitioner of Le Mars, Iowa, died at his home in that city, March 9, from cancer of the stomach, after an illness of eight weeks, aged 65.

**Joseph Ilowiecki, M.D.** University of Erlangen, Germany, 1882, who came to Detroit, Mich., in 1888, and was a prominent figure in Polish social and political circles in that city, died from heart disease, February 22, after an illness of more than a year at Skallierzyce, near Posen, Poland.

**Louis B. Tuckerman, M.D.** Long Island College Hospital, Brooklyn, N. Y., 1877, a prominent physician of Cleveland, Ohio, and a member of the American Medical Association, died at his home, March 5, after an illness of six weeks, from an intestinal complication, aged 54.

**Charles O. Carpenter, M.D.** Berkshire Medical College, Pittsfield, Mass., 1860, a veteran both of the Navy and Army in the Civil war and a well-known practitioner of Holyoke, Mass., died from pneumonia, at his home in that city, March 7, after an illness of six days, aged 63.

**John H. Morton, M.D.** Marion-Sims College of Medicine, St. Louis, Mo., 1897, a practitioner of Courtland, Cal., was drowned while on his way to make a professional call, March 2. He was a member of the American Medical Association.

**A. Lee Barron, M.D.** Memphis Hospital Medical College, Memphis, Tenn., 1898, a physician of Sweetwater, Ala., was shot and instantly killed in a quarrel over family affairs, at Sweetwater, March 7. He was about 30 years old.

**Charles D. Hill, M.D.** Medical School of Maine, Brunswick, 1880, a member of the American Medical Association, and a physician and surgeon of high standing, died at his home in Bethel, Maine, from typhoid fever, March 7, aged 47.

**William W. Collins, M.D.** University of Michigan, 1852, for 38 years a physician of Albion, Mich., and at one time president of the State Medical Society, died at his home, March 7, from paralysis, after an illness of six years, aged 77.

**Jarvis E. Smith, M.D.** College of Physicians and Surgeons, New York, 1854, a leading practitioner of Wayne County, N. Y.,

died at his home in Clyde, March 9, from abdominal cancer, after an illness of several months, aged 73.

**Hunter St. John, M.D.** College of Physicians and Surgeons, New York, 1886, who had recently moved from Minneapolis, Minn., to Pittsburg, Pa., died in the West Penn Hospital in that city, March 2, from heart disease.

**George M. Saul, M.D.** Cooper Medical College, San Francisco, a native of Petaluma, Cal., but who recently settled in Hawaii, died at the hospital in Honolulu, February 17, from typhoid fever, aged 26.

**N. A. Lancaster, M.D.** Medical College of Virginia, Richmond, 1898, a planter and practitioner of the Palmyra neighborhood, La., was drowned by the capsizing of the steamer Providence, March 12.

**Joseph P. Kelley, M.D.** Bellevue Hospital Medical College, New York, 1888, who had practiced since his graduation in Providence, R. I., died at the Rhode Island Hospital in that city, March 6, aged 37.

**Alpheus H. Julian, M.D.** Medical College of Indiana, Indianapolis, 1879, a well-known physician of Janesville, Cal., died from pleuro-pneumonia at the Alameda Sanatorium, February 22, aged 49.

**James McLaren, M.D.** Medical Department of Victoria College (Rolph's School), Toronto, a veteran medical practitioner of Ontario, died at Deer Park, a suburb of Toronto, March 7, aged 78.

**William H. Chapman, M.D.** University of Alabama, Mobile, 1873, a prominent physician of Geneva, Ala., died at his home in that place, March 5, from paralysis after a prolonged illness.

**Thomas Cave, M.D.** Washington University, St. Louis, 1872, an esteemed physician of Antwerp, Ohio, died at St. Louis, where he had gone to be operated on for cancer, March 6.

**William H. Presby, M.D.** Dartmouth Medical College, Hanover, N. H., 1887, a practitioner of Salem, N. H., died February 27, after a long illness, from paralysis, aged 45.

**Joseph T. Kirkpatrick, M.D.** Jefferson Medical College, 1877, an influential citizen and popular practitioner of Tunnel Hill, Ga., died at his home in that place, March 1.

**Andrew C. Rankin, M.D.** Starling Medical College, Columbus, Ohio, 1852, a retired physician of Chicago, died at his home after a surgical operation, March 5, aged 75.

**Charles Blank, M.D.** University of Munich, Germany, 1845, who had practiced medicine at the same address in St. Louis, for fifty years, died at his home, March 9, aged 80.

**Samuel S. Rogers, M.D.** University of Pennsylvania, 1849, an eminent physician of Western Pennsylvania, died at his residence in Millsboro, February 28.

**W. F. Ball, M.D.**, an old practitioner of Mantua Station, Portage County, Ohio, died at his home in Darrowville, near Akron, March 1, aged 65.

**George W. Jackes, M.D.** Toronto University, 1888, died suddenly at his home in Eglinton, Toronto, March 7, from apoplexy, aged 51.

**John Storrs Hall, M.D.** Milwaukee Medical College, 1897, died at his home in Ripon, Wis., March 4, from pneumonia, aged 31.

**William E. Brickhouse, M.D.** University of Pennsylvania, 1851, died recently at his home in Belle Haven, Va.

**Alf. H. Blackman, M.D.** Barnes Medical College, St. Louis, 1900, died at his home in Junction, Ark., March 4.

**Elias Smith, M.D.** University of Michigan, 1866, died at Whitmore Lake, Mich., March 6.

## Book Notices.

**MOSQUITO BRIGADES and How to Organize Them.** By Ronald Ross, F.R.C.S., D.P.H., F.R.S., Walter Meyers Lecturer in Tropical Medicine. Cloth. Pp. 100. Price, \$1.05. New York: Longmans, Green & Co., 1902.

This little volume is the result of most recent researches and discoveries in regard to the dissemination of some of the most important diseases that afflict mankind, especially in the warm or tropical climates. It is a book that ought to have a wide territorial circulation and one that should be read by every medical colonist and public health officer in a country where malaria exists. The author speaks with positiveness, and as an investigator he has earned the right to have his opinions respected. The author commends American methods in Cuba

as compared with the slow and comparatively inefficient methods of the English colonial authorities. It must be remembered, however, that what has been done there has been done under military government and the ordinary machinery of the law was somewhat in a condition of suspended activity, the more rapid military methods taking its place. There is no doubt, however, that sanitary organization and service is yet largely a matter of the future and that much requires to be done to bring about a better state of things, not only in British possessions, which are particularly criticised, but also in our own country and everywhere where the enforcement of sanitary measures depend on civil and political authorities. The book is a timely and valuable one.

**CHEMICAL PATHOLOGY IN ITS RELATION TO PRACTICAL MEDICINE.** By C. A. Herter, M.D., Professor of Pathological Chemistry in the University and Bellevue Medical College, New York. In one 12mo volume of 454 pages. Cloth, net, \$1.75. Philadelphia and New York: Lea Brothers & Co.

This work consists in a series of lectures delivered at the University and Bellevue Hospital Medical School during the sessions of 1899, 1900 and 1901. They give a very favorable impression of the thoroughness of the course, though the author modestly says that he has only aimed to sketch the leading characters of the pathologic and physiologic processes, without describing them fully or systematically. The student who has absorbed the instruction here given ought to be thoroughly competent, so far as these particular subjects are concerned, to enter upon the practice of medicine. Each chapter concludes with a brief enumeration of the leading articles on the subject, which will be useful to the student for reference, accompanied, besides the titles, by some short abstracts of the articles enumerated. The book is excellently indexed and is throughout a valuable text-book on its special subject.

**MUNICIPAL ENGINEERING AND SANITATION.** By M. N. Baker, Ph.B., C.E., Associate Editor of *Engineering News*. Cloth. Pp. 317. Price, \$1.25. New York: The Macmillan Co. 1902.

The need of a work of this kind brought up to date is obvious. Its intent is to furnish information, as the author says, to that large and rapidly growing class of persons who as officials and citizens are trying to improve municipal conditions. Every citizen should have some idea of the subjects here considered; for some of them come directly under his eye in almost every phase of civic life. If some of the ideas here advanced were generally adopted our cities, both large and small, would be very much more desirable places of residence than they are. The author's sensible opinion in regard to municipal extension, for example, could be very profitably read by the citizens of some of our municipalities within the last few years. We consider the work not strictly a medical one, but one for general reading and would be glad to bespeak for it a wide circulation.

### February Meeting of the Board of Trustees.

Pursuant to a resolution adopted by the Board of Trustees at the June meeting directing the Secretary of the Board to publish in *THE JOURNAL*, for the information of the members of the Association, a synopsis of the business transacted at each meeting, the following is respectfully submitted:

The Board of Trustees met in regular meeting Feb. 21-22, 1902, at Chicago, with the President, Dr. Hoppel, in the Chair, Dr. Johnson, Secretary. All members of the Board were present except Dr. Rodman, who was absent on account of illness.

The minutes of the previous meeting were presented and approved. The Treasurer, Dr. Newman, presented his annual report together with the report of the Public Auditor, which showed the finances of the Association to be in excellent condition, and the circulation of *THE JOURNAL* increasing. The report will be read at the Saratoga meeting before the House of Delegates.

Several accounts were presented to the Trustees for approval which were incurred in connection with the personal office of some of the officers of Sections. These were disallowed, and

the Secretary directed to notify the Chairmen and Secretaries of the various Sections that they must pay their own expenses, and that the Association will not be responsible for such expenses; further, that where specific appropriations are made, that amount shall not be exceeded.

In connection with *THE JOURNAL* office, it was found necessary, in consequence of the increased work, to purchase an automatic feeder and folder, also another printing press, the necessity for which being clearly demonstrated to the Board of Trustees. Considerable time and discussion was given to the matter of advertising in *THE JOURNAL*, and it was decided that advertisements of external remedies should be rigidly scrutinized, and that all such should be subjected to the same rule governing the admission to space in *THE JOURNAL* which applies to the publication of internal remedies, and further, that no advertisement of proprietary remedies shall be advertised in *THE JOURNAL* if such remedies are advertised in the lay press. Several firms who had made application for space in *THE JOURNAL* were notified by the direction of the Board that their advertisements would not be accepted unless they positively agreed to abide by the regulations of the Trustees. The editor was instructed to continue his individual efforts and carefully edit all advertisements before permitting them to appear in *THE JOURNAL*. A vote of thanks of the Board was tendered to the editor, Dr. George H. Simmons, for his faithful and efficient services and successful conduct of *THE JOURNAL* and the office of Secretary of the American Medical Association during the past and previous years.

In consequence of the present overcrowded condition of the printing office of *THE JOURNAL*, and a notification from the owners of the building that a considerable advance would be demanded on the present rental, the Board considered it imperative in the interests of *THE JOURNAL* and the American Medical Association to provide more space for the printing plant and offices. The following preamble and resolution was adopted:

WHEREAS, The present building rented by the Association for the publication and business of *THE JOURNAL* is wholly inadequate in space on account of the increased business demands, and whereas, no more space can be obtained in the building at present occupied, it was moved and carried, that the property located on the northeast corner of Indiana Street and Dearborn Avenue, in the City of Chicago, measuring 80 by 100 feet, be purchased for the use of *THE JOURNAL* and the other business of the American Medical Association.

The matter of securing the new site for *THE JOURNAL* had been carefully studied and investigated since the early fall by each member of the Board of Trustees, particular attention and investigation being carried on during this time by the resident trustee, Dr. Ingals, who has been untiring in his efforts in behalf of the interests of the Association. At a comparative additional outlay, it was decided at the earliest possible moment to remodel a portion of the property and transfer *THE JOURNAL* plant. Every detail with respect to title in the building and legal transfer to the Association was discussed and arranged for. All these matters will be fully set forth in the annual report of the Board of Trustees at the Saratoga meeting.

The Transportation Committee reported progress, and that their special aim was to secure a one-fare rate for the round trip with a time extension and the abolition of the annoying 50-cent fee which was inflicted upon the members of the Association at the St. Paul meeting. The annual report of the Board of Trustees was read and approved and ordered to be presented at the next meeting of the Association.

The propriety and advisability of the American Medical Association adopting a designating flag to be known as the flag of the American Medical Association, which shall fly over the headquarters of the American Medical Association at their annual meetings, was discussed, and the Secretary of the Board was requested to bring the matter up before the Association at the next meeting. After considering a number of minor matters and details, the Board adjourned to meet with the Association at Saratoga.

H. L. E. JOHNSON, M.D.,  
Secretary Board of Trustees.

## Societies.

### COMING MEETINGS.

American Association of Pathologists and Bacteriologists, Cleveland, O., March 28-29, 1902.  
 Medical Association of the District of Columbia, Washington, April 1, 1902.  
 Tri-State Medical Society of Iowa, Illinois and Missouri, Chicago, April 3-4, 1902.  
 Tennessee State Medical Society, Memphis, April 8, 1902.  
 Florida Medical Association, Tampa, April 9, 1902.  
 Western Ophthalmological and Oto-Laryngological Association, Chicago, April 10-12, 1902.  
 Medical Association of the State of Alabama, Birmingham, April 15, 1902.  
 Medical Society of the State of California, San Francisco, April 15-17, 1902.  
 Medical Association of Georgia, Savannah, April 16, 1902.  
 Mississippi State Medical Association, Jackson, April 16, 1902.  
 South Carolina Medical Association, Spartanburg, April 16-17, 1902.  
 Medical and Chirurgical Faculty of Maryland, Baltimore, April 22, 1902.  
 Association of American Physicians, Washington, D. C., April 29-30, 1902.

 International Association of Railway Surgeons, St. Louis, Mo., April 30 and May 1 and 2, 1902.  
 American Gastro-Enterological Association, Washington, D. C., May 2, 1902.  
 Nebraska State Medical Society, Omaha, May 6-8, 1902.  
 Texas State Medical Association, Dallas, May 6-9, 1902.  
 Kansas Medical Society, Lawrence, May 7-9, 1902.  
 American Therapeutic Society, New York City, May 13, 1902.  
 Utah State Medical Society, Salt Lake City, May 13-14, 1902.  
 New Mexico Medical Society, Albuquerque, May 14, 1902.  
 Oklahoma Territory Medical Association, Oklahoma City, May 14-15, 1902.  
 Arkansas Medical Society, Little Rock, May 14-16, 1902.  
 New Hampshire Medical Society, Concord, May 15-16, 1902.

**Hennepin County (Minn.) Medical Society.**—The first annual banquet of this Society was held in Minneapolis, March 3. Dr. Henry L. Staples was toastmaster and Drs. James B. Herriek and A. J. Ochsner of Chicago were the guests of honor.

**Somerville (Mass.) Medical Society.**—The annual election of officers and banquet of this Society were held, March 6. Dr. George A. Miles was re-elected president; Dr. Frederick G. Smith elected vice-president, and Dr. Arthur R. Perry, secretary and treasurer.

**Hardeman County (Tenn.) Medical Association.**—The physicians of Hardeman County met at Bolivar, March 5, and organized a county medical association, with Dr. John P. Douglass, president; Dr. Hugh W. Tate, vice-president, and Dr. Robert W. Tate, secretary, all of Bolivar.

**Tri-State Medical Society of Iowa, Illinois and Missouri.**—The tenth annual meeting of this Society will be held at Chicago, April 3 and 4, under the presidency of Dr. John C. Murphy, St. Louis. Dr. William B. LaForce, Ottumwa, is secretary, and Dr. Emil Ries, Chicago, chairman of the Committee of Arrangements.

**Floyd County (Ind.) Medical Society.**—This Society held its annual meeting at New Albany, March 6, at which Dr. Francis A. Mitchell was elected president; Dr. Edwin L. Sigmond, vice-president, and Dr. Charles P. Cook, secretary and treasurer, all of New Albany. The Society resolved to give a banquet to the members of the Country Practitioners' Society at the large room in St. Edwards' Hospital set apart for the use of the physicians. The banquet will be given May 3, and the Society has appropriated \$100 to meet the expenses of the entertainment.

**American Association of Urologists.**—This Association was organized, February 22, essentially for the purpose of further development of the study of the urinary organs and their diseases. Gynecologists who embrace renal and vesical surgery in their work are among the founders, as there are several gentlemen who devote themselves to the microscopy and chemistry of the urine, as well as a number of practitioners interested in the study of the kidney from a medical standpoint. The Association consists of active, corresponding and honorary members, and is in great measure modeled upon the plan of the Société Française d'Urologie, modified to suit American circumstances and conditions. Thus, whenever possible, the branch associations will hold their meetings on the same evenings as does the parent association in New York—the first Wednesday in each month. The work of the Association is principally clinical, for the demonstration of new methods of the technique of examination and treatment. The annual meeting of the Association will be held on the last day and the day following the an-

nual meeting of the American Medical Association. The officers of the Association are: Dr. Ramón Guiteras, New York, president; Dr. William K. Otis, New York, vice-president; Dr. John Vanderpoel, New York, treasurer; Dr. Ferdinand C. Valentine, New York, secretary, and Dr. Austin D. Mabie, New York, assistant secretary.
